Instruction to Authors
Greetings from Chettinad Health City Medical Journal!

It gives me immense pleasure and privilege in writing the editorial for this issue of the journal which focuses on the field of Ophthalmology.

The perspective article on Bayesian medicine enlists the importance of scientific diagnosis based on notion of probability and evidence based approach. The other perspective article on glaucoma screening focuses on various modalities and importance of glaucoma screening from community level to advanced hospital based investigations for early glaucoma diagnosis.

The original article on glaucoma awareness among medical doctors focuses the importance of continuing medical education as a tool for updating the knowledge. The article on endometrial thickness highlights the embryo quality rather than the endometrial thickness on successful implantation. The article on argon laser hyaloidotomy in management of premacular subhyaloid haemorrhage is interesting. The article on low responders in assisted reproductive technology gives the information regarding demographical profile of the patients.

The review article on acute and chronic otitis media highlights the importance of early treatment and its complications. The article on Calcium hydroxide reviews the applications, advantages and disadvantages of the same in the field of Endodontics. The other review article on dentistry gives a valuable information about the association between oxidative stress and oral malignancies.

Two of International Case reports on Vascular disorders i.e. Aortic dissection in young male body builder and spontaneous recanalization of occluded internal carotid artery is highly interesting and informative.

There are interesting case reports on acute retinal necrosis, Bisphosphonates induced uveitis, atypical unilateral Ocular Myasthenia from Ophthalmology Speciality.

Classroom on Anti-VEGF and its indications in ophthalmology is informative. The article from the pages of history highlights the invention and development of Intraocular lenses a major breakthrough in Cataract surgery.

In conclusion this edition of the journal highlights the ophthalmology subspecialty from history to recent advances with other medical and dental specialties. I hope it would be an academic feast for all the readers.

Abstract
Faulty diagnosis is often at the heart of medical treatment gone wrong. The root cause of this is that the medical practitioner is averse to a lengthy diagnosis process and relies exclusively on intuition and prior experience to arrive rapidly at a diagnosis. The purpose of this article is to advance a method of scientific diagnosis that would yield the highest probability of success. The method relies on a notion of probability that was introduced a few centuries ago. Using this method, it is possible to quantify the degree of confidence in one diagnosis relative to the degree of confidence in another differential diagnosis. The method provides an objective metric to differentiate between two competing diagnoses and select the correct diagnosis based on the strength of the evidence and findings. Adoption of the method would potentially improve the standards of medical treatment available in our country.

Key Words: Clinical diagnosis, Evidence-based medicine, Differential diagnosis, Bayes' theorem, Conditional probability, Likelihood ratios

Introduction
Thomas Bayes was an 18th century English theologian who laid down the foundations for an alternative, possibly authentic, interpretation of probability. Through the famous theorem that bears his name, he established a method for probability inference which factors the history of occurrence of the event in predicting the chance of its future occurrence. Using this interpretation, it is possible to update prior beliefs in the light of new relevant evidence in a precise manner. The Bayesian approach facilitates the quantitative integration of new sample information with old data to assess and refine our understanding of the states of nature.

Bayes' theorem is an elementary formula for calculating conditional probabilities, i.e., the probability of something given something else that has happened. For example, let us postulate a certain hypothesis H to explain some phenomena. Let the prior probability (before any measurement or observation has been made) of H being the true explanation be \( p(H) \). What is the posterior probability of the validity of hypothesis H in the light of acquisition of some new data D for the same phenomena? Following Bayes' theorem, this is given by:

\[
p(H|D) = \frac{p(D|H)p(H)}{p(D)} (1)
\]

where \( p(H|D) \) is the required posterior probability, \( p(D|H) \) is the likelihood of the data D given the hypothesis H, and \( p(D) \) is the overall likelihood of the data D under any hypothesis. From this, the theorem's key insight emerges, namely that a hypothesis is strengthened by unbiased data that its truth renders objectively probable. This idea is the foundation of Bayesian inference, which is applied to estimate the posterior probability of a given hypothesis in the context of new evidence. In the following, we will see that the heart of evidence-based medicine follows Bayesian tenets.

Diagnostic Reasoning
The diagnostic process is based on the clinical interview between the doctor and the patient. The clinical interview is subject to the same difficulties that bedevils any dialogue, even with an empowered patient. When we communicate our thoughts to others, we use descriptive terms with shared meanings. It is this notion of shared meanings that makes possible the idea of human communication. A diagnosis is the title we attach to a portrait of affliction. This might be pictured with varying degrees of meaning by different medical professionals, depending on the interpretation of the available evidence recorded in a particular patient. There will be substantial variation between what medical professionals imagine when a diagnosis is discussed. This in turn depends on what they have read, their personal experience, and research experience. As a matter of convention, the label for a given disease is used to connote the essence of the disease as generally understood. This motivates the need to delineate diagnostic envelopes specific to each disease. In developing diagnostic labels, we translate the 'particular' evidence from a specific patient and generalise the findings to evidence for a generic diagnosis. The sum of evidence would be deducing the probability of a diagnosis. Arguably (or inarguably) medicine is a probabilistic art, the aim being to maximise the probability of cure. As William Osler remarked, "Variability is the law of life, and as no two faces are the
same, so no two bodies are alike, and no two individuals react alike and behave alike under the abnormal conditions which we know as disease."

Intuitive Approach to Diagnosis

Most doctors use a non-transparent reasoning process. The diagnostic process need not involve conscious reasoning, it could be entirely intuitive. This seems to involve recognising combinations of signs and patterns of findings subconsciously and which suggest or confirm a diagnosis. When analysing the thought processes of doctors with long years of experience, it becomes evident that choosing a diagnostic lead (called a ‘pivot’) was key to the explanations of senior physicians in making a diagnosis. In a team setting, the team’s consensus opinion might have been recorded. The way that one’s own mind (or a colleague’s) worked to reach the diagnosis might be impossible to explain. The intuitive approach to diagnosis emphasizes the subconscious aspect of the diagnostic method. It is a skill that could be trained and improved by experience. Practice confers a degree of automaticity to rapidly recognise the constellation of signs, symptoms and findings as suggesting a diagnosis. Over time, this could become second nature just like recognising someone’s face. However attractive this approach, it has its limitations, namely that it tends to calcify with time and fails to keep pace with the advances in medical knowledge. Over-reliance on this approach would subject the diagnostic process to unintentional, sometimes grave, slips. These considerations motivate the need for a ‘transparent’ reasoning process.

Evidence-Based Approach

If a few or handful of differential diagnoses do not spring to mind readily, it is a paramount ethical obligation to employ a ‘transparent’ reasoning process. At the end of it, one might examine the outcomes of the non-transparent and transparent thought processes and see if they agree or not. If they are at variance, the doctor might wish to revise his/her opinion of the possible diagnoses. Unfamiliar situations frequently arise however experienced one becomes, which means that the transparent approach will be of permanent value. Transparent reasoning is a directed approach to solving diagnostic problems. It involves identifying an aggregate of specific which could be matched with a certain diagnosis. This could be initiated by selecting one diagnostic lead but not necessarily be the presenting complaint or the first finding the doctor sees. Multiple diagnoses would be consistent with the lead. All the diagnoses consistent with a lead are called differential diagnoses. The key duty of the physician’s art is to arrive at the correct diagnosis from the set of several competing differential diagnoses. By practising evidence-based medicine, the doctor would be validating the proposed diagnosis with an orthogonal mental process, just as we would double-check a calculation by permuting the symbols in an allowed manner. The transparent evidence-based approach verifies the clinical diagnosis and could take either the passive form or the stronger active diagnosis.

Evidence-Based Passive Diagnosis

Evidence-based passive approach involves thinking about each of the patient’s findings in turn and to consider if there is only one diagnosis that is common to each list of differential diagnoses. If there is only a single diagnosis common to a number of findings, it follows that the diagnosis will be probable, i.e. it will occur very frequently in a group of patients with those findings. Zeroing in on the diagnosis involves the identification of evidence confirmatory of a single diagnosis. A diagnosis could be confirmed in different ways. Here it is useful to distinguish between necessary and sufficient criteria. To illustrate with an example, in order to make a diagnosis of ectopic pregnancy, it is obvious that the subject is female and not male. If the patient is not female, then the patient lies outside the diagnostic envelope. Such an invariable diagnostic finding is termed a ‘necessary’ criterion. But the finding of necessary criteria may not be sufficient for confirming a diagnosis. If at least one sufficient criteria of a diagnosis is present, then the diagnosis becomes a candidate diagnosis. A confirmatory finding delineates the envelope of patients with the diagnosis. The multiplicity of findings present the ‘definitive criteria’ of the diagnosis, which are both sensitive and specific to those with the diagnosis. In other words, they are necessary as well as sufficient for the diagnosis. The evidence-based approach to diagnostic confirmation requires us to choose the ‘confirmatory’ test which could be shown superior to rival tests based on the balance of responder patients and those not responding to the treatments directed at the diagnosis. Essentially we would like to optimize the response rates in patients, the critical component of which is the determination of the correct diagnosis.

The best findings are those that maximise the frequency of successful diagnosis. The balance of probability of the finding modifies the likelihood of the diagnosis. If the finding is indicative of the pursued diagnosis but less so of another competing diagnosis, the pursued diagnosis becomes more probable relative to the competing, alternative diagnosis. In tandem with the earlier findings, the combined set of evidence would adduce correspondingly more weight to the pursued diagnosis. The same arguments hold for the finding that is not very representative of the pursued diagnosis. In this case, one of the competing diagnoses might gain in favour, and eventually replace the earlier pursued diagnosis.

Evidence-Based Active Diagnosis

Diagnoses could be actively pursued by searching for findings that would gradually confirm the pursued diagnosis. Absent such confirming findings, the tentative diagnosis could be progressively discounted, and another candidate diagnosis could take its place. The process is initiated by looking at the chart of findings and selecting one lead with the minimal list of consistent differential diagnoses accounting for the maximum fraction of patients with the lead finding. The other findings from the total evidence are used in the process of refining the diagnosis. If a finding has been shown to have a small number of differential diagnoses and these diagnoses account for a very high proportion of patients with that finding, then this would be evidence
of its ability to act as a good lead during the differential diagnostic process. In order to differentiate between the diagnostic categories, the physician has to choose a diagnosis to chase, which is called the postulated diagnosis. This should be the most probable diagnosis or dangerous diagnosis (to avoid delay). To put this framework on a precise footing, a mathematical treatment is necessary. We seek a measure of the ability of a test/finding to function as a differentiator of a pair of competing diagnoses. If a finding increases the likelihood of one diagnosis while simultaneously decreasing the likelihood of a competing diagnosis, then intuitively that finding would help to discriminate between the diagnostic pair.

The evidence-based method is a quantitative approach to differentiate between the competing diagnoses so that some become more probable and others less probable. The index of this ability to discriminate between two diagnoses is measured as simply the ratio of the conditional likelihoods of the two diagnoses given the finding. This ratio is different from the plain ‘likelihood ratio’ which is defined as simply the frequency of a finding in patients with a confirmed diagnosis divided by the frequency of the same finding in all those confirmed not to have that diagnosis. This ratio refers to a specific pair of differential diagnoses, and is thus termed a ‘differential likelihood ratio’. If this differential likelihood ratio (R) is significantly greater than one, then the finding could be said to improve the odds of the differential diagnosis under question. In general, if R is significantly different from one, then the finding favours one diagnosis over the other whereas if R = 1 the finding is neutral with respect to the two diagnoses. The relationship between empirical observations and the theoretical diagnosis is quantified using Bayes’ theorem. Let p(H1) be the prior probability of the diagnosis (given the lead finding F1), and p(H2) the prior probability of the differential diagnosis. Given another finding F2, the corresponding posterior probabilities are calculated using Bayes’ theorem:

\[ p(H1|F2) = \frac{p(F2|H1)p(H1)}{p(F2)} \]  

(2)

\[ p(H2|F2) = \frac{p(F2|H2)p(H2)}{p(F2)} \]  

(3)

The net effect of this procedure is to update the evidence for the diagnoses under consideration and identify those whose evidence has weakened in the light of the finding F2 and the estimates of the prior probabilities of the diagnoses given the diagnostic lead. The differential likelihood ratio between the competing diagnoses is given by the ratio of equations (2) & (3):

\[ \text{Diff. Likelihood ratio} = \frac{p(H1|F2)}{p(H2|F2)} \]  

(4)

The differential likelihood ratio obtained above is an objective indicator of the fitness of the diagnosis being chased relative to the competing differential diagnoses in the context of a specific finding and certain prior findings. A single diagnosis would be a final diagnosis if it could explain all the patient’s findings, otherwise at least two diagnoses would be needed, for example in comorbid conditions. A strong differential likelihood ratio provides general evidence of a finding’s ability to perform well as a differentiator during the diagnostic process. Given this background, we could objectively characterise the diagnostic lead as that finding with the maximal differential likelihood ratio. Auxiliary findings used in the diagnostic process provide further confirmatory differential likelihood ratios (or progressively discount the putative diagnosis in favour of some competing diagnosis). Bayesian estimation provides an objective method to revise the confidence in a particular diagnosis, eventually resulting in treatment decisions with better outcomes.

Conclusions

It is clear that scientific methods of diagnosis are the best answer to the plague of misdiagnosis that dominates medicine today. In the current scenario where new diseases are emerging, chances are even greater for the physician to fall into a diagnostic trap. Scant attention paid to the diagnostic process could equate to medical negligence and malpractice, and would lead to harm to the patient. The evidence-based approach with its solid foundation in Bayesian analysis is the way forward to resolving the diagnosis in difficult cases. The art of diagnostic detection could nearly match forensic criminology in its complexity, a fact attested by the popular fictional detective whose character was modelled on the diagnostic prowess of the physician Joseph Bell. Bayesian medicine holds the key to systematic diagnosis and captures the soul of evidence-based detection. It is the necessary criterion for the advancement of precision medicine.

Glaucoma Screening

Premnath G*

*Asst. Professor, Dept. of Ophthalmology, Chettinad Hospital & Research Institute, Chennai, India.

Introduction

Glaucoma is one of the leading causes of preventable blindness. Due to the asymptomatic nature in early stages, the diagnosis is missed quite often. This leads to irreversible loss of vision, thereby reduction in quality of life. As per estimation there are more than 60 million cases of glaucoma worldwide and 20 million more are expected to get added by 2020. Approximately 14% of total blindness is due to glaucoma. Around 50% of glaucoma cases are undetected. Chennai glaucoma study has observed that more than 90% of the cases are unidentified. As of now glaucoma has no cure. Hence early detection and treatment is the mainstay in management of glaucoma and prevention of blindness.

Objective

The objective of screening is to pick the disease early and to prevent the potential blindness by appropriate management. Effective and economically beneficial approach is needed for early detection and further management. From the patient’s point of view, regular eye checkup is the mainstay of early detection.

Modes of screening

Screening can be done either at community level or at institutes.

Community screening

People can be screened at the community level by conducting regular eye camps. Torch light examination with intra-ocular pressure (IOP) measurement by non-contact tonometer or rebound tonometer and ophthalmoscopy can pick most of the cases. Those with high IOP and/or findings suggestive of glaucoma should be referred to hospitals for further management. Combined ophthalmoscopy and tonometry for all persons and perimeter for high risk persons has a sensitivity of 80%.

Screening at hospitals

Govt of India has recommended opportunistic screening for people aged above 40 yrs visiting outpatient department. Other means of screening include intra-ocular pressure measurement for all patients at first visit and conducting regular glaucoma screening programs etc. Family members of glaucoma patients need to be screened regularly. Glaucoma suspects will undergo detailed examination and investigations to quantify the damage and commencement of treatment.

Screening tests

All tests are focused on the optic nerve head to detect the presence of either structural damage or functional damage.

Tests to detect functional damage

Tonometry and perimetry are used to detect functional damage of the optic nerve. Goldmann Applanation Tonometry (GAT) is the gold standard to measure the intraocular pressure. Standard Automated Perimetry (SAP) is used to detect the visual field defects whereas Frequency Doubling Perimetry (FDT) which requires lesser time can be used mainly for screening purpose.

Tests to detect structural damage

Optic Disc Photography, Heidelberg Retinal Tomography, Optical Coherence Tomography, Retinal Nerve Fiber Layer (RNFL) Analysis and Scanning Laser Polarimetry (SLP) are used to quantify the structural damage.

The sensitivity and specificity of each test individually is not promising. As no single test is conclusive, diagnosis and management cannot be finalized on a single test result. Combination of multiple methods somewhat aid in effective screening. Sight savers study combined IOP, FDT and a questionnaire (three tests) and the sensitivity and specificity were found to be 88.6%, and 57.1% respectively. The ultimate aim is to find out effective and cheap methods for screening.

Challenges

There is no definite method or combination of methods for effective screening. Further studies are needed to customize the optimal combination of screening tests to detect glaucoma at a much earlier stage. Till then we should target the high risk individuals. Following people are at high risk for glaucoma:

- Aged 40 yrs and above.
- With family history of glaucoma.
- High intraocular pressure.
- African Americans (for open-angle glaucoma).
- East Asians and people with East Asian ancestry (for closed-angle glaucoma).
- Myopes (greater risk for developing open-angle glaucoma).
Perspective Article  Glaucoma Screening

Glaucoma Screening

Hypermetropes (greater risk for developing closed-angle glaucoma).
Those taking corticosteroid in any form.
With diabetes/hypertension.

Conclusion

Screening for glaucoma not only prevents avoidable blindness but also improves the medical quality of the patient and the economic quality of the society. Though glaucoma screening is tough, the result i.e. early detection and management to prevent blindness is rewarding. Regular eye examination is proved to be the effective way of screening glaucoma as recommended by various studies. Greater focus should be on the family members as there is 10-fold increase in the risk of glaucoma among the relatives. Better education and awareness about glaucoma go a long way in the detection of the dreaded disease.

Oxidative Stress a Link to Periodontal Disease and Oral Cancer

*Shankarram V, **Joysonmoses, **Lakshmi Narayanan, **Tamil Selvan
Reader *, Professor**, Department of Pedodontics, Thai Moogambigai Dental College, Chennai, India.

The study has the following objectives:
1. To detect the oxidative stress in periodontitis
2. To compare the oxidative stress between oral cancer patients and periodontitis
3. Group of periodontitis (n=25)
4. Group of oral cancer (n=25)
5. Group of healthy controls (n=25)

Materials and methods

Chettinad Health City Medical Journal 2016; 5(1): 07 - 09

Abstract

The oral cavity is an entry of other systems of the body; it should not be viewed as an isolated area. Diseases that it lays down can have systemic impact and significantly affect the quality of life of individuals who suffer them. Periodontal disease is one of the oral health problems that most often affect the global population, lack of treatment leads to loss of tooth organs and consequently alters the digestion and nutrition, without considering other relevant aspects like phonation, aesthetics and social or emotional impact. The importance of periodontal disease has raised possible bidirectional relationships with systemic diseases such as diabetes, metabolic syndrome and cardiovascular disease. We address herein the role of oxidative stress in the pathogenicity of periodontal disease. In the same context, another disease that has become relevant in our days is the oral cancer. Detection of the reactive oxygen species in the periodontitis patients and oral cancer patients reveal the relationship between the oxidative stress in periodontitis and oral cancer patients.

Key Words: Oxidative stress, Periodontal disease, Oral cancer

Introduction

Oxidative stress is the systemic disturbance caused by the increased Reactive oxygen species a biological system’s ability to readily detoxify the reactive intermediates or to repair the resulting damage. Disturbances in the normal redox state of cells can cause toxic effects through the production of peroxides and free radicals that damage all components of the cell, including proteins, lipids, and DNA. Oxidative stress from oxidative metabolism causes base damage, as well as strand breaks in DNA. Base damage is mostly indirect and caused by reactive oxygen species (ROS) generated, e.g. O2•− (superoxide radical), OH• (hydroxyl radical) and H2O2 (hydrogen peroxide). In humans, oxidative stress is thought to be involved in the development of Asperger syndrome, ADHD, cancer, Parkinson’s disease, Lata disease, Alzheimer’s disease, atherosclerosis, heart failure, myocardial infarction, fragile X syndrome, Sickle Cell Disease, lichen planus, vitiligo, autism, infection, chronic fatigue syndrome. Periodontitis. Epidemiological data show that the incidence of this neoplasm has been increasing in several countries. The impact of oral cancer on patients, who suffer it, is devastating. The role of oxidative stress in the development of this disease and some alternatives for its treatment, are topics addressed in this brief. Periodontitis and oral cancer are two oral diseases and a sample of the plethora of effects that oxidative stress may have at local and systemic level. So this study analyses the reactive oxygen species in saliva samples there by proving their role in periodontitis and oral cancer.

Objectives

The study has the following objectives
1. To detect the oxidative stress in periodontitis patients and oral cancer patients
2. To compare the oxidative stress between oral cancer patients and periodontitis

Study groups

The case control study was done in department of periodontology under the ethical clearance from Dr. MGR UNIVERSITY And Research Institute three groups n=25 was selected
1. Group of periodontitis (n=25)
2. Group of oral cancer (n=25)
3. Group of healthy controls (n=25)

Materials and methods

The saliva samples were collected from the three groups and stored in the plastic bottles, and the study done in regenix laboratory, Chennai. Oxidative stress status was assessed by measuring the total antioxidant capacity (TAOC) and biomarkers of oxidative stress 8-hydroxy-2-deoxyguanosine (8-OHdG) and malondialdehyde (MDA) in saliva and the activity of some of the main antioxidant enzymes glutathione peroxidase (GPx) and superoxide dismutase (SOD).

GPx and SOD activities and TAOC levels were determined using a competitive ELISA kit (Cayman Chemical Company; Item numbers 703102, 706002, and 709001, resp.) according to the manufacturer’s instructions. MDA levels were measured with NWLSS Malondialdehyde Assay (Northwest Life Science Specialities; Catalog number NWK-MDA01) following the manufacturer’s instructions. 8-hydroxy-2-deoxyguanosine (8-OHdG) levels were measured with NWLSS High Sensitivity 8-OHdG ELISA (Northwest Life Science Specialities; Catalog number NWK-MDA01) following manufacturer’s instructions.
Statistical Analysis

All results shown are expressed as mean and 95% confidence interval. Statistical comparisons between groups were assessed by Mann-Whitney or Kruskal-Wallis tests. The linear trend between groups was analyzed by the Jonckheere-Terpstra test. Multivariate linear regression predictive models were made with the different oxidative stress parameters as the dependent variable. The independent variables were age, gender, smoker (as confounding variables).

Results

We obtained a highly significant elevation of all oxidative stress marker levels except for that of SOD. Periodontitis group and oral cancer denoted increased oxidative stress level. Therefore, the presence of oxidative stress in periodontitis and oral cancer is significant compared to healthy group.

Discussion

The pathological events which lead to the destruction of the periodontium during inflammatory periodontal disease have been related to the effect of the imbalance between oxidants and antioxidants in patients with periodontal disease20.

ROS are generated predominantly by PMN during an inflammatory response21. It has been suggested that the bacterial species in subgingival plaques and the PMN response are important factors in the changes in periodontal disease status. An increase in ROS leads to the destruction of periodontal tissue, and it is one of the most important causes of periodontal disease. The present study has demonstrated significative changes in oxidative stress by measuring different oxidative stress markers (8-OHdG, MDA, GPx, SOD, and TAOC) that increased with worsened periodontal status.

The involvement of free radicals in cancer development has been studied for 3 decades, and there is sufficient evidence that implicates theirs in the multistage theory of carcinogenesis. Free radicals are products of the oxidation-reduction systems of the cell and its participation in cellular metabolic functions is essential for cell survival. A classic example is the electron transport chain in mitochondria. However, in what pathological conditions, free radicals can become deleterious?

In fact, what are the results of its harmful effects. They are proposed to cause diverse DNA alterations like: punctual mutations, DNA base oxidations, strand breaks, mutation of tumor suppressor genes and can induce overexpression of proto-oncogenes22. Several works explore the levels of oxidative stress in patients with oral cancer23 most of them quantified the products of lipid-peroxidation (mainly malonaldehyde) and contrast them with the activity of antioxidant enzymes or exogenous antioxidants levels in blood or even saliva. The results agree that there is an imbalance between the high amount of free radicals and insufficient antioxidant system activity. Added to this, some researchers have observed that high levels of lipid-peroxidation combined with low levels of thios and antioxidant status, correlate with poor survival rate in patients with oral cancer24. It should be added that oxidative protein damage participates in facilitating the development of cancer. The present study has demonstrated significative changes in oxidative stress by measuring different oxidative stress markers (8-OHdG, MDA, GPx, SOD, and TAOC) that increased in oral cancer.

Our results agree partly with Canakci et al.25. In salivary samples from 30 patients with chronic periodontitis and 30 periodontally healthy controls, these authors obtained higher salivary 8-OHdG and MDA levels and lower salivary antioxidant activities that seem to reflect increased oxygen radical activity during periodontal inflammation.

Conclusion

Certainly, the main limitation of the study has been the small sample size, but the study could confirm the possible linear correlation between markers of oxidative stress and the periodontitis and oral cancer. Further studies with larger sample size should continue this line of research. In conclusion, the determination of oxidative stress levels could be a potent tool in controlling the development of periodontitis and tool in detection of oral cancer.

Survey of Awareness about Glaucoma Among Medical Doctors of A Medical College and Tertiary Care Hospital in South India

Premnath G*, Manoj Vasudevan**, Pandurangan R***, Swathi****

*Asst. Professor, **Associate Professor, ***Professor, ****Post Graduate student, Dept. of Ophthalmology, Chettinad Hospital & Research Institute, Chennai, India.

Dr (Maj) G. Premnath graduated from Govt. MK Medical College, Salem. After a short stint in Indian Armed forces, he did his post graduation in Ophthalmology from Command Hospital (Air force) and Clinical Fellowship in Glaucoma from Narayana Nethralaya, Bangalore. His fields of interest are Cataract, Glaucoma, Medical retina and Ophthalmic research.

Chettinad Health City Medical Journal 2016; 5(1): 10 - 12

Abstract

Purpose: Glaucoma is one of the leading causes of blindness. Various studies have highlighted the lack of awareness among general population which leads to non-diagnosis or late diagnosis of glaucoma. Very few studies have been done among medical professionals. The present study was conducted to evaluate the level of awareness and knowledge about glaucoma among the doctors in a medical college and tertiary care hospital. Methods: A structured questionnaire-based survey was conducted among 350 doctors of a tertiary health care institution to evaluate the level of awareness and knowledge about glaucoma. Results: Of the 350 doctors enrolled for the survey, responses from 319 (91.14%) participants were evaluated. 110 (34.48%) were specialists and 209 (65.52%) were non-specialists. 18% of the participants think that glaucoma is always symptomatic and 12.7% think it is painful always. Surprisingly 23.1% (n=70) of medical doctors think that central vision is affected first. 20.7% think that lost vision can be restored by treatment. 35.1% think that glaucoma is directly related to blood pressure and 18.4% think that diabetes is not a risk factor. Conclusion: Knowledge about glaucoma among doctors is poor. Doctors of a medical college are instrumental in propagating the information of the irreversible blindness that could arise from delay in glaucoma diagnosis and treatment. Hence there is a dire need to update their knowledge on glaucoma.

Key Words: Glaucoma, Awareness, Medical doctors

Introduction

The general public believe that doctors are aware of all diseases and rely on them for medical related issues. Most often non-ophthalmic doctors are the first point of contact for many patients with eye related issues. Hence it is imperative that all doctors are made aware of glaucoma, it’s early stages, like glaucoma. Glaucoma is a progressive optic neuropathy characterized by optic nerve head damage and visual field damage with or without increased intra ocular pressure (IOP). The disease with prevalence varying from 2.6% to 4.1% invariably results in blindness if left untreated. Glaucoma related blindness is preventable only with early detection and regular treatment. This study is conducted to evaluate the level of awareness and knowledge about glaucoma among doctors of a medical college and tertiary care hospital in South India. No studies have been reported so far from this part of the country.

Materials and Methods

This study was conducted in Chettinad Hospital and Research Institute and Chettinad super specialty hospital which is a tertiary care medical college hospital located in South India. This cross sectional study included 350 medical doctors including interns from various specialties. Study was conducted after obtaining the approval from the institutional ethics committee. After obtaining an informed consent, all participants were given a structured questionnaire and asked to complete the presence of one of the investigators. All the participants were educated, the questionnaire was printed in English. We initially validated first 10 questionnaires to look for any potential changes and proceeded with other participants. 350 doctors filled the questionnaire out of which 319 responses were valid. Incomplete questionnaires were excluded from evaluation. All the data were entered and analyzed with SPSS. Categorical variables were analyzed with the independent t-test and Pearson’s chi-square test. A P value of less than 0.05 was considered statistically significant.

Inclusion criteria: All doctors including the interns of Chettinad Hospital and Research Institute and Chettinad Super Specialty Hospital who are volunteer for the survey.

Exclusion criteria: Ophthalmologists, Residents and interns working in the Dept of Ophthalmology, CHRI.

Results

Responses from 319 participants were analyzed. The mean age of participants was 38.24+ 8.54. 110 (34.48%) were specialists and 209 (65.52%) were non-specialists.
It was surprising that 03 participants had not heard about glaucoma (Table 1). Most of the doctors were aware that glaucoma is associated with increase in intra-ocular pressure that damages optic nerve head. 4.7 % of doctors thought otherwise (Table 2).

18% of the participants think that glaucoma is always symptomatic and 12.7 % think it is painful always. Out of 303 participants who think that glaucoma can affect vision, 23.1% think that central vision is affected first. 2.2% think that there is no treatment for the disease. 20.9% think that lost vision due to glaucoma can be restored. 35.1% think that glaucoma is directly related to blood pressure and 18.4 % think that diabetes is not a risk factor (Table 3).

| Patients with glaucoma always have symptoms     | 57  | 18.0| 255 | 80.7| 4          | 1.3|
| Glaucoma is always painful                      | 40  | 12.7| 271 | 85.8| 5          | 1.6|
| Glaucoma can affect vision                       | 303 | 95.9| 7   | 2.2 | 6          | 1.9|
| Type of vision affected in glaucoma              | 214 | 70.6| 70  | 23.1| 19         | 6.3|
| Is there any treatment for glaucoma?             | 306 | 96.8| 7   | 2.2 | 3          | 0.9|
| Without treatment glaucoma will cause blindness | 297 | 94.0| 15  | 4.7 | 4          | 1.3|
| Lost vision can be restored by treatment         | 66  | 20.9| 236 | 74.7| 14         | 4.4|
| Glaucoma is directly related to blood pressure   | 111 | 35.1| 193 | 61.1| 12         | 3.8|
| Is DM a risk factor for glaucoma?                | 246 | 77.8| 58  | 18.4| 12         | 3.8|

55.38% of participants rightly thought that family history is the strong risk factor for glaucoma whereas 20.89 % thought it is an age-related problem. Around 12% thought refractive error is the strong risk factor (Table 4). All the values were statistically significant.

Discussion

Various studies have been conducted among patients and general public3–6, but very few among health care personnel7, 8. Probably there are no studies conducted among medical doctors in this part of the country. In a study conducted among workers in a Nigerian tertiary health care institution, awareness and knowledge were compared among clinical and administrative staff (n=120 each). No statistically significant difference about the knowledge of the aspect of vision that is first affected by glaucoma, the painless nature of glaucoma among most Africans and the irreversible nature of glaucoma-related blindness, were found8.

Parul et al, had surveyed physicians and nurses of a medical college in North India (n=119). Our study has been conducted among medical staff including interns and a larger number of participants were included (n=319). The results are comparable to that study.

Surprising facts that have surfaced with regards to knowledge of doctors in this study are as follows:-

16% of the medical doctors have not undergone an eye check-up till date. Though they are working at a place with easy access to health care, there is barrier to...
undergo eye examination. 18% think that glaucoma is always symptomatic. 23% think that glaucoma affects central vision first. 20% think that lost vision due to glaucoma is reversible. Respectively 20% and 16% think that age and refractive errors are the strong risk factors for developing glaucoma.

Even though the medical doctors are working in a tertiary care hospital, their knowledge about glaucoma is disheartening. These findings expose the lacuna in our medical curriculum in terms of preventive medicine. In addition to the fact that all medical doctors are expected to update their medical knowledge, the state should also organize education programmes to promote awareness and refresh knowledge about all common diseases particularly of those which are asymptomatic at earlier stages.

Conclusion
Among medical doctors, though the awareness is good, the knowledge about glaucoma needs up-gradation. Loss of touch with the subject among specialists of non-ophthalmic specialties is known to be the major issue. Periodical Continuing medical education programmes and lectures should be conducted in health care institutions to sensitize the doctors.

Does the endometrial thickness really matter in Assisted Reproductive Technology Cycles - A Retrospective analysis

Gayathri Devi SS *, N. Pandiyan**, Radha Pandiyan***

*Junior Consultant, ** Chief Consultant & HOD, Department of Reproductive Medicine, *** Senior Consultant, Chettinad Super Speciality Hospital, Chennai, India.

Dr. Gayathri Devi graduated in Medicine from Coimbatore Medical college in 1999 and Post Graduate in MS (OG) from Sree Siddharta Medical College, Tumkur, Karnataka in 2005. She has completed her Fellowship in Andrology and Reproductive Medicine in 2013 at Chettinad Health City and currently working as Junior Consultant in the Department of Reproductive Medicine, Chettinad Hospital and Research Institute, Kelambakkam since February 2013. She has presented several research papers in national conferences.

Corresponding author - S.S.Gayathri Devi (gayathridevi.ss@gmail.com)

Abstract

Aim: The objective of the study was to observe the thickness of endometrium on HCG trigger day during Assisted Reproductive Technology (ART) cycles and correlating it with pregnancy outcome. Materials and Methods: From September 2008 to December 2014, 57 patients undergoing assisted reproduction cycles were retrospectively analyzed for the pregnancy outcome in relation to endometrial thickness. The study was done in the Reproductive Medicine department, Chettinad Hospital and Research Institute, Kelambakkam. All fresh Intra Cytoplasmic Sperm Injection treatment cycles using short flare protocol were included and categorised into two groups based on the pregnancy results: 1. Group A (pregnant), 2. Group B (non-pregnant). Results: The mean endometrial thickness in the groups A and B were 10.02 + 1.46 (7.1 to 13.4 mm) and 10.40 + 2.19 (7.8 to 19 mm) [P < 0.447, Not significant]. The clinical pregnancy rate was 42.10% and the implantation rate was 22.81%. Pregnancy rate was good probably because of the selection of grade 1 embryos and limiting the age of patients to <35yrs. Conclusion: From our study, the endometrial thickness is not the deciding factor for the successful implantation of human embryo. We also infer that thin endometrium of < 7 mm is an unlikely occurrence in ART cycles unless there is pathology in the uterus.

Key Words: Endometrial thickness, Embryo, Implantation, Pregnancy outcome.

Background

Despite numerous papers analyzing the influence of endometrial thickness in influencing pregnancy outcome, the issue remains unclear. Compared to the escalating cost, the outcome of pregnancy is low in ART/ICSI cycles which mandates the reevaluation of the predictive factors for success in ART.

Introduction

Implantation of embryos is the final and most critical step in assisted reproduction. Both embryo quality and endometrial receptivity play a vital role in implantation of embryo. The assessment of endometrial receptivity is by simple 2D ultrasonographic (USG) examination during stimulation. Since USG is a simple, non-invasive, patient friendly and reliable technique for the evaluation of endometrium, it is commonly employed.

For the implantation to take place, priming of endometrium occurs in each and every menstrual cycle. The communication between the blastocyst and the endometrium is expected to be closer if the implantation is to be successful. If these cyclic changes are prevented by abnormalities of endometrium, there are less implantation and more miscarriages.

The relationship between thickness or pattern of endometrium and the receptiveness of the uterus has been analyzed by many authors. Some studies reported with increased endometrial thickness pregnancy rates are less. Some other studies reported that with increase in endometrial thickness, the pregnancy rates also increase. Both the endometrial thickness and pattern are analysed in few other studies to prognosticate the pregnancy outcome of ART. Recent studies analyzed the endometrial blood flow by doppler studies to predict the pregnancy outcome in ART. But some others concluded that there is absence of influence over pregnancy outcome by the endometrial thickness and pattern.

In the first systematic meta-analysis, the predictiveness of the role of endometrial thickness over ART outcome was investigated. The chances of clinical pregnancy was significantly less in patients when the endometrium was < 7 mm compared to > 7 mm (23.3% vs 48.1%) and OR was 0.42 (95% CI 0.27 – 0.67).

Endometrium:

Distance between endometrial-myometrial junction of one side to the other is measured as the endometrial thickness. The measurement is taken in the longitudinal axis on the day of hCG trigger by using two dimensional transvaginal ultrasound.
The thickness of the endometrium at early follicular phase in the antero-posterior (AP) view is approximately 5-7 mm. It becomes triple line around ovulation and is about 8-12 mm. Echo pattern becomes homogeneously hyper-echoic in luteal phase. Remarkable changes take place in the endometrium after ovulation. By 13 days post ovulation, the endometrium clearly differentiates into 3 zones:
1. Stratum basalis
2. Stratum spongiosum
3. Stratum compactum

The cardinal morphologic change around implantation is the formation of edema of the endometrial stroma which is on days 21 - 22 of the menstrual cycle. More production of prostaglandin by the endometrium occurs due to sex steroids. Ultimately the permeability of the capillaries are increased with rise in prostaglandins. There are receptors available for the sex steroids in the vasculature of the endometrium.

Implantation

Implantation is defined as the adhesiveness of the blastocyst with the epithelial lining of uterus and subsequently invading the epithelium, occurring approximately 18-19th day of menstrual cycle. More production of prostaglandin by the endometrium occurs due to sex steroids. Ultimately the permeability of the capillaries are increased with rise in prostaglandins. There are receptors available for the sex steroids in the vasculature of the endometrium.

Materials and Methods

Study population: From September 2008 to December 2014, 57 patients who underwent ART cycles were retrospectively analyzed for the pregnancy outcome in relation to endometrial thickness after excluding the factors discussed later. The study was done in the department of Reproductive Medicine, Chettinad hospital and research institute, Kelambakkam.

Methodology

All fresh ICSI cycles using short flare protocol who underwent oocyte retrieval and also transfer of embryos were included.

Inclusion criteria:
1. Age < 35 yrs
2. First cycle ART
3. Only short agonist protocol
4. Normozoospermia
5. Transfer of three, grade 1 embryos

Exclusion criteria:
1. Cycles using donor oocytes / embryos
2. Cycles using cryopreserved embryos
3. Presence of known uterine anomalies
4. Presence of hydrosalphinx
5. Ovarian stimulation method other than the short agonist protocol.
6. Male factor infertility

Procedure:
The pituitary was down regulated with short GnRH agonist (flare) protocol from D2 of menstrual cycle to HCG trigger and stimulation of ovaries was achieved with urinary gonadotrophins. When at least three follicles reached ≥ 18 mm by 2D USG, oocyte retrieval was planned. The clinician measured the thickness of the endometrium and recorded in the patient’s case sheet. Inj. HCG trigger was given and the oocytes were retrieved 35-36 hours later. ICSI was carried out to achieve fertilization. Embryo transfer was planned post oocyte retrieval (D2/D3/D5). Luteal phase was supplemented with progesterone vaginal pessaries from the day of OPU and continued till day 14 post embryo transfer. Two weeks after positive βHCG, USG was planned. When fetal cardiac activity was present, clinical pregnancy was confirmed.

Ultrasound examination

The maximum thickness of the endometrium in the longitudinal plane was measured on the day of HCG trigger. Based on pregnancy results, all cycles were categorised into:
1. Group A (pregnant)
2. Group B (non-pregnant)

Statistical Analysis

Continuous data are measured as Mean ± SD and analysed. To test the equality of mean values of two groups, independent samples t-tests are used and P <0.05 was considered as statistical significance. To compare the differences between two groups when the characteristic of interest is qualitative in nature, Mann Whitney tests are applied. IBM SPSS (Version 21.0) software was used for statistical analysis.

Results

All the 57 women who met the inclusion criteria were analyzed in our study. The patients were between 25 and 34 years of age with the mean of 30.86 yrs. The baseline characteristics of the two groups, with pregnancy (group A) and without pregnancy (group B) are shown in table 1. Comparison of baseline characteristics revealed no statistical difference in parameters such as age, BMI and period of infertility in the pregnant and non-pregnant groups. There was also no significant difference seen in the basal FSH and total AFC (Antral Follicle Count).
Both groups have comparable baseline features. Group A patients had mostly secondary infertility (46.43%) and group B had predominantly primary infertility (72.41%). The predominance of primary infertility in group B and secondary infertility in group A is not significant (NS) statistically (P<0.144) and the patients were selected based on random allocation. In Table 2 and Fig 2, the cause of infertility in the two groups was given. The major cause of infertility in both the groups were tubal factor (46.43 and 44.83%).

### Table 2 - Cause of infertility and Endometrial thickness

Cause of infertility did not influence the endometrial thickness. (P<0.672, NS)

**Fig 2 - Major cause of infertility in both the groups was tubal factor.**
Table 3 shows the clinical findings of the two groups. No significant difference was observed in the duration of stimulation, amount of gonadotrophins utilized for stimulation and the number of dominant follicles. Though the number of oocytes retrieved and mature oocytes (MII) were more in group B, it is not significant statistically.

The endometrial thickness on the day of HCG trigger was between 7.1mm and 19 mm with the mean of 10.21mm. The mean endometrial thickness in the groups A and B were 10.02 + 1.46 (7.1 to 13.4 mm) and 10.40 + 2.19 (7.8 to 19 mm) and it was not significant statistically (P < 0.447). In our study, no patient had endometrial thickness < 7 mm. Both the groups had almost similar duration of ovarian stimulation (11.18 + 2.23 vs 10.72 + 2.07). The total dose of gonadotrophins used was comparable between both the groups (3334.82 + 1074.22 vs 3300 + 1091.46). The total number of embryos transferred was 3, grade 1 embryos which is similar in both the groups. It is evident that the cause of infertility has no influence on endometrial thickness.

</tr>
</tbody>
</table>

Table 3 - Clinical Characteristics

Pregnant and non-pregnant groups show no significant difference in the clinical characteristics.

Endometrial thickness has no influence over pregnancy outcome.

Table 4 and fig 3 shows the day of transfer with positive outcome and endometrial thickness. The mean day of embryo transfer for group A was 3.57 and group B was 3.66 which were similar between both the groups and not significant statistically. The pregnancy rate and clinical pregnancy rate of the study group were 49.12% and 42.10% respectively. The implantation rate was 22.81%. Pregnancy rate is good probably because of the selection of grade 1 embryos and limiting age of patients to < 35yrs.

</table>

Table 4 - Day of embryo transfer with positive outcome and Endometrial thickness

Single and twin pregnancies were 12 (42.86 %) and 12 (42.86 %). The number of miscarriages was 3 (10.71 %) and we had one (3.57%) biochemical pregnancy with D5 transfer. The single/twin pregnancies were in the range of 8 to 11 mm endometrium mostly. Also we had miscarriages and biochemical pregnancy in that range of endometrium. Hence we could not arrive at a conclusion regarding influence of endometrial thickness and the outcome of pregnancy.
Discussion
Since the introduction of ART by Prof. Edwards and Mr. Steptoe in 1978, the success rate hovers around 40 to 45%. Hence, to improve the success rate, various factors are analyzed from time to time. The pioneering work on human implantation was done by Hertig and colleagues 50 years ago. Since then different opinions have emerged regarding implantation and now recently the focus is shifted to endometrial receptivity to identify the receptors. The present day receptor mediated model which estimates the window of implantation of the endometrium was described by Yoshinga and Wilcox. Different ART cycle parameters and the outcome have been analysed and endometrial thickness is one such parameter which has been evaluated by several authors. Adequate preparation of the endometrium is essential for a successful implantation to take place. Endometrial thickness reflects the enlargement of endometrium in the absence of uterine pathology.

In a study by Noyes et al. (1995), analysis of 516 IVF cycles showed more pregnancies with the endometrial thickness of > 9 mm. Weissman et al. (1999), found in a study that with thickness of >14 mm the implantation rate was less. Also they found that the miscarriage rate was more when it was >14 mm on the day of trigger injection. Likewise, in a study by Dickey et al., more biochemical pregnancies were found with endometrial thickness of >14 mm. No pregnancy with endometrial thickness >12 mm was reported by Rashidi et al. However, there are case series which reported successful pregnancies when endometrial thickness was ≥ 20 mm. Quintero reported a single case of successful pregnancy when endometrial thickness was ≥ 20 mm. However, later studies found absent influence of endometrial thickness on outcome of pregnancy. Also in the latest study by Fang et al. (2016), no unfavourable pregnancy outcome when endometrial thickness >14 mm was observed.

In our study, one patient with endometrial thickness >14 mm was negative for pregnancy. Hence it is difficult to comment on influence of increased thickness over pregnancy outcome. When there is an endometrial pathology as in Asherman’s syndrome, the usual endometrial changes do not occur. Hence there is less implantation and more miscarriages. Though there are many studies showing successful pregnancies in cycles where the endometrial thickness of <4 mm was observed, we have not seen a patient with <7 mm endometrial thickness in 830 ART/ICSI cycles since 2008 in our centre. Hence endometrial thickness <7 mm is an unusual occurrence in ART patients unless there is presence of uterine anomalies/pathology.

In our study majority of women had endometrial thickness >8 mm with the mean of 10.21 mm. Our study does not conclude any adverse effect of endometrial thickness >14 mm over pregnancy. No conclusive evidence from our study with regard to pregnancy mishaps like miscarriages. Nor does an ideal endometrium (8 to 11 mm) guarantee a pregnancy. Though implantation of the embryo happens in the endometrium, we are not able to conclude that the thickness of the endometrium really has an influence on the favorable outcome of ART.
On the contrary, we feel the quality of embryos has a vital role in deciding the implantation of the embryos. Hence, it seems obvious that the process of implantation is much more complex than what can be determined by a single and simple USG measurement of the endometrium\(^\text{35}\).

**Conclusion**

We have limited the confounding factors which may have effect over implantation and then assessed the influence of endometrium on implantation of embryo. From our study, the endometrial thickness is not the deciding factor for the successful implantation of human embryo. We feel that a good quality embryo has more potential to implant in any reasonable environment and grow further. We also infer that thin endometrium of < 7 mm is an unlikely occurrence in ART cycles unless there is pathology in the uterus. Limitations of our study are it is a retrospective study and small number of patients analyzed.

Profile of Low Responders in Assisted Reproductive Technology -
A Retrospective Study

Krithika Devi*, Radha Pandiyan**, Pandiyan N***

*Consultant, Nova IVI Fertility Centre, Chennai, **Sr.Consultant, ***Prof & HOD, Dept. of Reproductive Medicine, Chettinad Super Speciality Hospital, Chennai, India.

Introduction

Despite the vast understanding of controlled ovarian stimulation protocols, there are still a group of women who do not respond well to ovarian stimulation and yield few oocytes at retrieval, resulting in few numbers of embryos and poor pregnancy rates.1

This low ovarian response is one of the most controversial and frustrating issues in Assisted reproduction. Though a variety of regimens have been tested to improve ovarian response, the results are not comparable and an ideal stimulation protocol does not exist, as homogenous population was not tested in any clinical trials.2-6. It is difficult to estimate the exact prevalence of low ovarian responders, because of its varied definition though reported to be 5-24% of patients undergoing Invito fertilization (IVF).7 This review will describe the profile of women who showed low response to ovarian stimulation in our study.

Definition

The pathogenesis, prediction and possible treatment options for low ovarian response have been published in numerous journals. Despite the wide spread use of the term low ovarian response to gonadotropins, no standard definition exists.8-11

First realistic attempt to standardize a simple and reproducible definition was presented at ESHRE scientific community held in Bologna in 201012. It is defined as low ovarian response when at least two of the following criteria were present:

(i) Advanced maternal age (≥40 years) or any other risk factor for low ovarian response

(ii) Previous low ovarian response resulting in less than 4 eggs to stimulation &

(iii) Abnormal ovarian reserve test (AMH 0.5-1.1 ng/ml or AFC 5-7).

In this definition the importance is given to the response to stimulation. Two episodes of low ovarian response after maximal stimulation are sufficient in the absence of advanced maternal age or abnormal ovarian reserve test to define low ovarian response.

Since it is the response to stimulation, it is essential to

Abstract

Aim: To analyse the various features (categorical and continuous) associated with low responders in Assisted Reproductive Technology (ART).

Materials & Methods: Design: Retrospective Study. Setting: Department of Reproductive medicine, Chettinad Hospital and Research Institute, Kelambakkam, Tamil Nadu, India. Patients: Out of 200 patients undergoing ART cycles (From January 2008 to March 2010) at Chettinad Hospital, 25 patients who had low ovarian response were analysed. Intervention: All of the 25 patients had been down regulated with GnRH analogue (Leuprolide acetate) 1mg in short protocol and stimulated with U. HMG/FSH with a minimum dose of 225 IU and for a period of 10 days. Main Outcome Measures: This review will describe the profile of women who showed low response to ovarian stimulation. Result: Incidence of low response was 12.5%. The profile of patients with low responders in our study showed mean age of 34.1 years, mean period of infertility of about 8.1 years, low antral follicular count, interestingly low response was also observed in women with proven fertility that is after tubectomy. Conclusion: Women with low response had low antral follicular count, higher basal FSH, Required higher dose and longer period of stimulation. Low ovarian response was observed in younger women also. Prior pelvic surgical history was observed in significant number of women.

Key Words: Low Responders in ART, Low ovarian response, GnRH analogue

Key Words: Low Responders in ART, Low ovarian response, GnRH analogue

Introduction

Despite the vast understanding of controlled ovarian stimulation protocols, there are still a group of women who do not respond well to ovarian stimulation and yield few oocytes at retrieval, resulting in few numbers of embryos and poor pregnancy rates.1

This low ovarian response is one of the most controversial and frustrating issues in Assisted reproduction. Though a variety of regimens have been tested to improve ovarian response, the results are not comparable and an ideal stimulation protocol does not exist, as homogenous population was not tested in any clinical trials.2-6. It is difficult to estimate the exact prevalence of low ovarian responders, because of its varied definition though reported to be 5-24% of patients undergoing Invito fertilization (IVF).7 This review will describe the profile of women who showed low response to ovarian stimulation in our study.

Definition

The pathogenesis, prediction and possible treatment options for low ovarian response have been published in numerous journals. Despite the wide spread use of the term low ovarian response to gonadotropins, no standard definition exists.8-11

First realistic attempt to standardize a simple and reproducible definition was presented at ESHRE scientific community held in Bologna in 201012. It is defined as low ovarian response when at least two of the following criteria were present:

(i) Advanced maternal age (≥40 years) or any other risk factor for low ovarian response

(ii) Previous low ovarian response resulting in less than 4 eggs to stimulation &

(iii) Abnormal ovarian reserve test (AMH 0.5-1.1 ng/ml or AFC 5-7).

In this definition the importance is given to the response to stimulation. Two episodes of low ovarian response after maximal stimulation are sufficient in the absence of advanced maternal age or abnormal ovarian reserve test to define low ovarian response.

Since it is the response to stimulation, it is essential to
have at least one stimulated cycle. However women with abnormal ovarian reserve test and advanced age can be considered as expected low responders13.

ESHRE consensus on the definition of low ovarian response was criticized as14 -
1. The study population was diverse
2. Detailed risk factors were not explained
3. Clear cut cut-off for the ovarian reserve test were not suggested especially, in case of Anti Mullerian Hormone
4. Bologna criteria was based on previous studies rather than scientific experiments
5. The number of oocytes were quantitative rather that qualitative and was not outcome (prognosis) based predicting the results of in vitro fertilization.

Aetiology of Low Ovarian Response
Beyond the well-established relation between advanced maternal age and low ovarian response to gonadotropins, there are number of other factors, which may be important15,16. Previous ovarian surgery, ovarian endometriosis, Pelvic inflammatory disease, systemic illness, radiotherapy, chemotherapy, chronic smoking, environmental factors, and specific conditions affecting the ovaries may all influence the ovarian response to gonadotropin stimulation17-22.

Short menstrual cycle, endometriotic cystectomy and chronic smoking have been associated to affect both the quantity as well as quality of retrieved eggs, hence the pregnancy rate23,24. Our study analyses the various features associated with Low responders in ART. Numerous categorical and numerical variables were analyzed in the study.

Materials and Methods
This is a retrospective study of 200 ART cycles between January 2008 and March 2010 at Department of Reproductive medicine, Chettinad Hospital and Research Institute, Kelambakkam, Tamilnadu, India. All of them had down regulation with GnRH analogue (leuprolide acetate 1mg) in a short protocol and stimulation with u-HMG/FSH with a minimum dose of 225 IU and for a minimum period of 10 days.

Several numericals such as age, body mass index (BMI), number of present children, number of previous IVF cycles, serum follicle stimulating hormone (FSH), total gonadotropin dose administered, number of total and mature oocytes, and number of embryos transferred and categorical variables (infertility diagnosis, period of infertility, previous ovarian surgery, tubectomy, abnormal menstrual pattern) were recorded.

The eligible cohort were women with follicular response of three or less dominant follicles on the day of HCG trigger. This group of women was taken as low responders and their association with other categorical and numerical variables was analyzed.

Results
The incidence of low responders was 12.5% [25/200] in our study group(Fig 1). The age distribution was 22 women < 40 years, 3 women > 40 years. Primary infertility was the predominant type in 80% women. Prolonged period of infertility was observed in 85% of women (> 5 years). We had interestingly 9 women out of 25 [36%] with history of pelvic surgeries/adhesions. Low response was seen in 3 women who had undergone tubectomy (Table 1). 2 out of 25 women[ 8%] had history of surgery done for endometriosis. Menstrual history was normal in 92% of women. BMI above 30 was observed in 16% of these women.

Stimulation dose of 300 IU of u- FSH/HMG per day for 10-15 days was used in the majority -76%. The total antral follicular count was less than 5 in 68% of women. Basal FSH value was >10 in 56% and <10 in 44%. Adequate endometrial thickness was seen in 88% of women. No oocyte was obtained in 9/25 women [36%] Fig 2. Only 9 women reached stage of embryo transfer [36%]. Some prior good responders showed a subsequent low response in repeat cycle [4 women] (Table 2).

Discussion
Ovarian age is an independent variable critically affecting IVF outcome, while chronological age assumes a less important prognostic role, once the diagnosis of diminished ovarian function has been made26-28.
theory is supported by previous reports that stressed that the age at which the ovarian reserve declines is highly variable and therefore age alone could have a limited predictive value with respect to reproductive potential. In fact, AFC and AMH Levels, as a measure of ovarian reserve, has been shown to be a better predictor of a woman’s chance to conceive than her chronological age.  

The authors declare no conflict of interest.

Abstract

Aim: Subhyaloid hemorrhage is usually a benign condition which does not cause much vision loss and usually will resolve spontaneously. Long standing premacular subhyaloid hemorrhage cause permanent loss of visual acuity as it involves the fovea. The aim of this study is to investigate the effects of drainage of premacular subhyaloid hemorrhage into the vitreous with Argon Green laser treatment. Materials and Methods: This study was conducted between February 2014 and March 2015. Six patients with premacular hemorrhage in one eye subjected to Argon Green laser to drain the blood into the vitreous cavity. The causes for hemorrhage were Anemic retinopathy (1 case), proliferative diabetic retinopathy (1 case), Terson syndrome (1 case), pancytopenia (1 case) and blunt ocular trauma (2 cases). Results: The mean size of pretreatment hemorrhage was 4.5 disc diameters (range 3.5-8.0). Visual acuity in all cases before laser treatment was hand movement to 6/60. There was rapid improvement of vision after laser treatment. Drainage was complete within one week and visual acuity improved dramatically. The mean follow-up was 12 months. No retinal damage or rebleeding except ILM folds (not significant) occurred due to the laser. Conclusion: Argon green laser posterior hyaloidotomy may be useful for draining a premacular hemorrhage into the vitreous cavity in selected cases as it is a non-surgical procedure. To establish this as a routine procedure, a randomized prospective study is needed to compare observation, primary vitrectomy, and Argon green laser treatment.

Key Words: Sub Hyaloids Hemorrhage, Argon Green Laser

Introduction

Subhyaloid hemorrhage is defined as a localized detachment of vitreous from the retina caused by the accumulation of blood, which can lead to sudden and severe loss of vision, when it takes place in the macular area. The various causes for Subhyaloid hemorrhage include retinal vascular disorders such as proliferative diabetic retinopathy, branch retinal vein occlusion, macro aneurysm, and age related macular degeneration; it may occur in hematological disorders also such as leukemia and chemotherapy induced pancytopenia or after retinal vascular rupture associated with physical exertion (Valsalva retinopathy). Valsalva retinopathy often occurs in healthy young adults due to lifting heavy things, straining in toilet, vomiting, coughing. Usually there will be spontaneous resorption of the blood entrapped in subhyaloid space. But sometimes it may take months and can cause permanent visual impairment due to pigmentary macular changes or formation of epiretinal membranes and toxic damage to the retina due to prolonged contact with hemoglobin and Iron. There are various methods available to treat premacular hemorrhage. These include conservative treatment, Argon Green laser hyaloiodectomy, pars plana deep vitrectomy and pneumatic displacement of hemorrhage by intravitreal injection of gas and tissue plasminogen activator. Puncturing the posterior hyaloid face with argon green or Nd YAG laser is a safe and easy alternative for releasing the entrapped subhyaloid blood into the vitreous. Consequently, the obscured macular area is cleared and resorption of blood cells is facilitated. In this study we evaluated 6 patients with subhyaloid hemorrhage treated with argon green laser hyaloidotomy.

Materials and methods

This is an interventional case-series in which 7 eyes of 6 patients with premacular subhyaloid hemorrhage were included between the period of one year (2014 to 2015) in Chettinad Hospital and Research Institute. Patients who gave their consent were included in the study and patients with other retinal hemorrhages were excluded. The patients were subjected to complete evaluation with detailed history taking. Pretreatment and post treatment examination included best corrected visual acuity, slit lamp microscope examination, intraocular pressure, and funduscopy. Fundus photographs were taken to measure the size of the subhyaloid hemorrhage by comparing with optic disc dimensions. After a written consent Tropicamide eye drop was applied to dilate the pupil and paracaine was used for topical anesthesia. ARGON GREEN laser was applied through a slit lamp and a Goldman three-mirror (Volk) lens with an average total energy of 500 mJ (range: 200 to 600 mJ). Laser was applied to the lowermost dependent part of the blood-containing...
subhyaloid pocket in order to enhance the blood release process and better protection of the underlying retina. Patients were periodically followed up on 2nd day, 1st week, 2nd week, and at the end of the study. The main outcome measured in this study were postoperative improvement in visual acuity and postoperative complications. The success rate in performing hyaloidotomy, releasing the entrapped blood into the vitreous cavity and its resorption also were recorded and analyzed.

Results
Totally seven eyes of 6 patients were included out of which 4 were males (60%) and 2 females (40%), with an average age of 33 ± 10.33 years (range: 31 to 67 years). One (66.7%) had diabetic retinopathy, two had blunt trauma, one (8.3%) had a pancytopenia due to chemotherapy, one had Terson syndrome and 1 (25%) was diagnosed with Anemic retinopathy as the main cause of their premacular hemorrhage. The mean pretreatment hemorrhage measured 4.5 ± 1.7 disc diameters. Argon green laser hyaloidotomy was successful in all cases and the trapped blood was released into the vitreous cavity and resorbed after a mean period of 10 (6 to 16) days. Preoperative visual acuity in the affected eyes of these patients ranged from hand movement to 6/60, which was improved from 20/40 to 20/20 postoperatively. Patients with the diagnosis of blunt trauma retinopathy achieved normal vision after treatment and the improvement was better when compared with others. Table 1 summarizes patients’ characteristics and postoperative results. In our study there were no special complications like rise in intraocular pressure, retinal and choroidal hemorrhage, macular hole, or retinal break noted in follow up period of 12 months.

Table 1: Summary of patients’ characteristics and postoperative results

Discussion
A subhyaloid hemorrhage is an intraocular collection of blood that remains contained in a self-created, previously nonexistent space, usually between the posterior limiting layer of the vitreous and the retina5.

Posterior hyaloidotomy was done using Argon Green laser in 6 patients who had premacular subhyaloid hemorrhage. The trapped blood was released into the vitreous and resorbed within 6 to 16 (average: 9) days in all of them. There was atleast 4 lines (Snellen chart) improvement in their visual acuity within 16 days of the laser in all of the cases6. In our study the visual improvement seen in trauma cases was better than other cases.

The best corrected visual acuity (BCVA) improved to
20/20 following laser in 4 out of 6 cases (66%). This can be explained by lack of retinal vascular lesions or any retinal pathology in the cases except for diabetic retinopathy.

In study by Ulbig et al, which included 21 patients with premacular subhyaloid hemorrhage laser hyaloidotomy was successful in 16 (76.2%) and visual improvement in all of them. This was similar to our study. Final visual acuity was better in patients with Valsalva retinopathy compared with other etiologies.

Similarly Rennie et al., also studied 10 patients with premacular subhyaloid and did Nd-YAG laser hyaloidotomy in 6 patients while he conservatively managed the other 4 patients. There was rapid improvement of hemorrhage in all the patients and there was no complication similar to ours.

In the study by Gabel et al, 3 patients were managed successfully with Nd-YAG laser hyaloidotomy and one patient with Valsalva retinopathy after military operation gained full vision postoperatively.

Fig 3: Showing Normal Fundus with Laser Mark after 1 Month of Treatment
Fig 4: Showing Subhyaloid Hemorrhage Due to Terson Syndrome Before Treatment
Fig 5: Showing Laser Marks and Drainage of Hemorrhage after Laser Treatment
Fig 6: Showing Pancytopenic Retinopathy in Right Eye
Fig 7: Showing Laser Marks and Drainage of Hemorrhage after Laser Treatment
Conclusion
As observed by our study and several previous studies we can conclude that Argon green laser hyaloidotomy is a simple, inexpensive outpatient procedure which is relatively safe compared with other more complex operations such as deep vitrectomy and its potentially serious complications.

There is a rapid visual recovery in majority of the patients and it can prevent long-term entrapment of blood and its adverse effects on macula including potential permanent loss of vision. However, the drawback of this study is lack of comparison between other methods. So further large centre clinical trials is necessary to compare the visual and functional outcomes between observation, laser and vitrectomy in subhyaloid hemorrhage.

Otitis Media and Middle Ear Effusion - An Overview

Deepti Pandey*

*Consultant, Otorhinolaryngologist, Shri Laxminarayan Marwari Multispeciality Charity Hospital, Varanasi, Uttar Pradesh.

Abstract

Otitis media and middle ear effusion are major health care burden across the globe. The prevalence in developing countries mostly exceeds the WHO stipulated emergency level of 4%. Failure of Eustachian tube function is key pathogenic element of effusion in middle ear cavity involving complex pathophysiology. Acute otitis media accompanies upper respiratory infection or allergy. Its acute symptoms almost always attract treatment yet, on resolution of acute stage effusion over brief period, occurs in middle ear cavity. Recurrences are driven by risk factors. Chronic effusion is not symptomatic but impairs hearing function that adversely affects intellectual and behavioural development of children. Untreated infection coupled to risk factors would cause supplicative otitis media and perforation of ear drum. The later accompanies purulent ear discharge, and threatening complication s for middle ear integrity and intracranial abscess and thrombosis. The narrative attempts to overview approaches to timely diagnosis and medical and surgical management in current practice for spectrum of the disease.

Key Words: Otitis media, Middle ear effusion, Chronic suppurative otitis media, Ear infection

Introduction

Otitis media (OM) simply means inflammation of middle ear. Hearing loss due to OM is worldwide public health issue. Acute otitis media complications occur in children and old while those due to chronic disease occur in young adults, particularly as cholesteatoma. Patients with intracranial complications remain hospitalized for long periods of time with significant disability and mortality. High incidence of OM in face of inaccurate diagnosis and possible serious sequel make it important health challenge. The disease spectrum may vary from self-limiting to prolonged and complicated disease.

Acute otitis media (AOM) is mostly due to infection and is among commonest maladies in paediatric outdoors. Spontaneous healing takes place in many during adolescence years, however intervening years cast significant impact on academic performance. Virtually all children by age of 6 may get at least one episode of otitis media. Most regions of developing countries have prevalence of otitis media above 4% constituting emergency as per WHO stratification.

Otitis media and Middle ear effusion

AOM involves rapid onset of symptoms and signs of up to three weeks duration. After an episode of AOM there is high incidence of persisting middle ear effusion of mean duration of 40 days. It is classified as recurrent acute otitis media (RAOM) if three episodes occur in six months or four in twelve months and there is otoscopic normalization during the inter-crisis period. Chronic otitis media with effusion (CSOM) indicates middle ear inflammation with liquid collection in middle ear space (ME). Chronic disease is variously stated as serous/secretory OM or glue ear. It implies presence of fluid in middle ear for three months or longer. Tympanic membrane is intact and there may not be signs and symptoms of infection. Middle ear effusion may be serous thin watery liquid, mucoid-thick, viscid, mucus-like liquid or purulent pus like liquid. Discharge from ear is termed otorrhoea.

Ventilation is essential for regulation of pressure within ME for optimal hearing function. Normal Eustachian tube (ET) structure and function protects ME from abnormal nasopharyngeal sound pressures and secretions. Pumping action of ET to drain ME fluid involves abnormal nasopharyngeal sound pressures and secretions. Pumping action of ET to drain ME fluid involves beginning of passive closure at ME end which progresses toward nasopharyngeal end. Eustachian tube (ET) has ability to open up during swallowing which equilibrates pressure of ME and nasopharynx. Posture also affects ET function. Elevation from horizontal position causes venous engorgement of the ET reducing air passage. Functionally and structurally immature ET as well as the immune system is determinant of susceptibility of babies to otitis media. Role of genetic predispositions have been suggested as well. Children with their short, floppy ETs can reflux nasopharyngeal secretion in to middle ear during an acute respiratory viral infection. Nasopharyngeal secretion cannot enter ME with normal ET function, as gas cushion entrapped in intact ME and mastoid air cell system opposes that.

Pathogenesis

Pathogens must enter middle ear cavity (ME), through ET from bacteria and virus reservoir in rhinopharynx.
The normal tubo-tympanum is immunologically protected not only by the adaptive immune system, but also by the mucociliary system and the selected molecules of innate immunity. Viruses in nasopharynx damage mucociliary function and facilitate nasopharyngeal bacterial adherence and colonization and subsequent entry into the ET. An obstructed ET leads to negative pressure in the middle ear following reduced ventilation. Such state when prolonged causes overgrowth of mucus producing cells and fluid transudation in the middle ear.

Bacterial and viral infection as well as sterile effusion stimulates release of proinflammatory cytokines from mucosal immune cells. Adhesion receptors in submucosa are up-regulated mediating lymphocyte invasion and accumulation, which secrete cytokines and other inflammatory mediators. The later affect leakage of fluid from mucosa. Nitric oxide and free radicals are implicated in persistent ME effusion at stage when there is vasculare engorgement and angiogenesis increasing mucosal blood flow. Increase of nitrogen in mircrocirculation adds creation of negative ME pressure.

When clearing function and immune system fails to eliminate them otitis media results. Mucus accumulation allows proliferation of infecting Streptococcus pneumonia and non-typename Haemophilus influenza. Bacterial endotoxin may impair mucociliary activity, induce effusion, enhance mucus production and cause mucosal metaplasia. Such changes help transformation of planktonik pathogens in biofilm. Biofilm bacteria are difficult to culture and resistant to antibiotics, hence long persisters. Emerging evidence indicates that, following upper respiratory tract infection, biofilm activity in the adenoid produces a cascade of immune mediators, causing inflammation and up-regulation of mucin genes in the middle ear mucosa, with associated reduction of ciliary function and clearance. It is likely that middle ear ventilation helps disrupt the biofilm infection by increasing and maintaining high middle ear oxygen tension.

Otitis media with effusion, OME is said to result from “hydrops-ex-vacuo” mechanism. It is postulated that failure of ET opening causes gas exchange from ME to microcirculation of mucous membrane. As per Doyle’s postulate, possible increase in circulating inflammatory mediators from local allergic reaction in nose or stomach mucosa inhibit alteration of ME-mucosal permeability and thus altered gas exchange. This results in under-pressure within the ME that enforces transudation and effusion. Upper respiratory infection may cause ET block inducing effusion as above. Allergic reaction also may adversely affect structure of ET mucus blanket.

Chronic supplicative otitis media is the chronic stage following AOM, when there is TM perforation and continuous discharge. CSOM pathogenesis involves loss of ME gas cushion due to TM perforation. In such state, allergic or inflammatory states of nasopharynx promote reflux of infected fluid through ET to ME. When tympanic membrane is perforated or following radical mastoidectomy, the gas pocket is lost. Nasopharyngeal fluid can now reflux through ET to ME. Similar mechanism is basis of otorrhea after tympanostomy tube insertion or mastoidectomy. Initially it is organisms as H. influenza and Streptococcus pneumoniae. With setting of otorrhea, organisms from external auditory canal such as staphylococci and pseudomonas invade ME causing chronic infection.

Risk Factors
Adenoids serve as bacterial reservoirs. Frequent upper respiratory infections predisposes to RAOM and COME by way of inflammation and harm to mucociliary movement of ET epithelium. This may lead to atelectasis of tympanic membrane-middle ear (the high negative middle ear pressure), sterile OME or acute bacterial otitis media. Passage of nasopharyngeal fluid through ET to effusion containing ME may create mixed state seen as recurrent acute bacterial otitis media. Bacterial biofilm formation on ME mucosa fosters chronic effusion state. Significant mucus content in ME effusion indicates antecedent acute infective otitis media.

Allergy is one of etiological factors of otitis media, as evident from strong association. The OME children have 4 fold higher incidence of atopic symptoms. In a study increased IgE in middle ear effusion was found in 14 of 32 children with allergic rhinitis in contrast to only 2 of 45 non allergic cases. Significant mucus content in ME effusion indicates immune competence also.

Epidemiology
Otitis media with effusion (OME) is most prevalent in children of 2 to 5 year age. The natural course shows constant improvement in half the sufferers over next three months. Recurrence is high in almost half the cases over a year period. The factors that cause persistence and recurrence in the victims need characterization for primary and secondary prevention.

Otitis media is universally present in infants with untreated cleft palate. Primary cause is failure of opening mechanism of ET. The risk factors influence one or more causal mechanisms viz. race, sex, age which influence structure and function of ET. Age affects immune competence also.

Age is important and several predisposing anatomical, physiological and immunological determinants make children vulnerable. Early first episode itself increases risk for recurrence and chronic otitis media. Male sex appears to have marginally higher susceptibility. Socio-economic strata are important determinants as well. ET obstruction may be acute or chronic. Periodic ET opening helps prevent accumulation of ME effusion. ET dysfunction is seen prominently during pregnancy and during puberty in female suggesting hormonal influence also. Significant hereditary determinants are understood from high familial aggregation of the disease.

Children with anatomical defects (cleft palate, submucous cleft), altered physiological defenses (ET dysfunction, barotraumas), congenital or acquired
immunologic deficiencies (immunoglobulin deficits, chronic granulomatous disease, AIDS, immunosuppressive drugs) are at vulnerable to severe and recurrent or persistent disease. Infants exclusively breast fed in first 3 to 6 months are somewhat less vulnerable. Crowded living conditions, poor sanitation and inadequate medical care have been associated with otitis media. Increased incidence associated with exposure to passive smoke is reported. Sulphur dioxides pollution of environment increases both pneumococcal diseases and otitis media. Seasonal preponderance with upper respiratory infections in winter is also seen.

**Diagnosis**

Redness of eardrum is relied as diagnostic sign of AOM. Most important distinction between OME and acute otitis media (acute suppurative otitis media) is that the signs and symptoms of acute infection (e.g. otalgia, fever) are lacking. Diagnosis cannot be based on symptoms alone because they are too vague. OME diagnosis, estimate of accompanying hearing loss and risk of complications critically determine development of quality screening, treatment and intervention programme. Specific subjective and objective measures help this.

Four characteristics of tympanic membrane, position, mobility, colour and degree of translucency are evaluated. Microscopic otoscopy is of utmost importance for examination of the ear. It also offers the possibility of documentation of the pathology. Pneumatic otoscopy is also a sensitive and specific method for the detection of otitis media. Opacification of the tympanic membrane can be frequently detected. Pneumatic otoscopy reveals either a retracted or convex tympanic membrane with decreased mobility. Tympanometry is useful for assessing tympanic membrane mobility and middle ear function. Pure-tone audiometry or visual reinforcement audiometry (VRA) can be used to diagnose mild hearing loss associated with OME in infants. Adjunct procedures in evaluating recurrent disease include X-ray of nasopharynx and nasopharyngeal fibroscopy to assess adenoid size, nasal examination (septum deviation, enlarged turbinates), immunologic evaluation, allergy testing, etc. Tympanocentesis is the gold standard to detect fluid in ME and sampling the same for culture or PCR typing is when there are craniofacial malformations, or the degree of hearing loss is disproportionate to clinical findings or when sensorineural hearing loss is detected, historical resolution CT and MRI scans are helpful to identify the middle ear abnormalities.

OME patients do not present primarily for hearing loss, instead poor speech and language development, inattentiveness in class, behavioural problems and reduced or poor social interaction with other children are the reported concerns. In most cases hearing loss is major sign or symptom. Some children also suffer balance problems and become clumsy. History of recurrent episodes of OM or developmental concerns and audiometric hearing loss detection facilitate diagnosis. Three month monitoring of hearing status helps decision for surgical intervention. Hearing in better ear at 25-30 dB or worse constitutes indication for surgery.

It is important to identify children at risk for possible developmental sequel of OME, including speech language delay, and behavioural problems. Children who develop OME and have additional disabilities including sensorineural hearing loss, autism, syndromes (eg. Down syndrome), learning disabilities as well as other conditions, are at greater risk of persistent OME and conductive hearing loss.

**Management perspectives**

Organisms causing AOM are Streptococcus pneumonia or Haemophilus influenza in over third of cases each. A quarter of cases are due to Moraxela catarrhalis. Rhinovirus infection contributes to prolong ME effusion. In half the instances S pneumonia is penicillin resistant.

50% of cases of OME, effusion is not sterile and PCR is positive in up to 75% for microbial DNA. Initial benefits of antibiotic therapy are only transient and hence not recommended as routine. There is limited evidence for short term improvement of OME with intranasal steroids. Currently only limited evidence exists on benefit of pneumococcal vaccine in OME prevention. It may be advised in cases with underlying predisposing factors.

Newly diagnosed OME in children is found to resolve in half the cases within 1 month, in three fourth cases by 6 month to around in 90 percent in one year. The recurrence rate is high and over some years 30 to 40 percent children suffer repeated episode. Most children with persistent OME require insertion of grommet tube. In older children nasal auto-inflammation is helpful before surgical help. Following grommet surgery, otorrhea can occur either following an upper respiratory infection or water contamination through the grommet. The tube may get blocked or extruded. Otorrhea responds to short course of antibiotic ear drops.

Chronic suppurative otitis media (CSOM), is chronic inflammation of middle ear and mastoid cavity with perforation of tympanic membrane and purulent discharge through same. The disease has usual beginning in childhood. CSOM is heavy disease burden in developing countries with reported 72 cases per 1000 population prevalence. Untreated CSOM has broad range of complications related to spread of infection in adjacent structures and damage of middle ear itself. The complication range from persistent otorrhea, mastoiditis, labyrinthitis, facial nerve palsy and intracranial abscess and thromboses. The aim of management is to achieve safe dry ear, eradication of disease and hearing improvement.

Early effective treatment helps avoid complications. Treatment can be medical therapy directed at eradication of pathogenic aerobic and anaerobic organisms. Cases resistant to medical therapy need surgical intervention. Uncomplicated CSOM treatment involves meticulous aural toilet (with suction /mopping up of ear debris and discharges followed by instillation of topical and systemic antimicrobial agent.

In CSOM Pseudomonas aeruginosa, Staphylococcus aureus, Corynebacterium, Klebsiella species cause infection. Anaerobes superve in in cholesteatoma.
Amoxicillin-Clavulanic acid is generally safe and effective antibiotic. Second generation cephalosporins eg, cefprozil, cefpodoxime, are effective on resistant S pneumoniae and group A Streptococci. Cefuroxime is also satisfactory for controlling H influenza. The antibiotics need be administered for 10 to 15 days. In half the cases effusion would persist.

Amoxicillin/ampicillin was more frequently used earlier but micro organisms display changing pattern of sensitivity to quinolones, cephalosporins and gentamycin. Ciprofloxacin drops are non ototoxic. Gentamycin drops though believed to possess ototoxicity are still useful as effective agent, since CSOM itself also causes sensorineural hearing loss. Keeping in view the high prevalence of S.aureus and P.aeruginosa and their susceptibility to quinolones (ciprofloxacin) and cephalosporin (ceftazidime), ciprofloxacin ear drops or systemic therapy of ciprofloxacin, piperclilnine or ceftazidime can be used safely in all age groups.

The study of microbial patterns and their antibiotic sensitivity determines the organisms prevalent in locations and can guide empirical treatment of the disease and its complications and also prevention of emergence of resistant strains. Control of environmental risk factors (breast feeding, passive smoke etc) makes sense in OME prevention. A causal relationship between allergy and OME has been suggested but not quantified. Management of inhalant and food allergy appears prudent. Inflammatory or infectious processes in nose, nasopharynx or paranasal sinuses also need control to avoid compromise of ET function by secondary mucosal edema. Opening of ET by autoinflation of nose has not proved beneficial.

**Surgical treatment**

Management decisions in children with OME depend on duration of effusion, laterality, and presence and severity of associated symptoms. Signs and symptoms that support clinical assessments may include: Mild intermittent ear pain and sense of fullness; Pain related rubbing of ear, irritability and sleep disturbance; inadequate response to sound in direction and extent; inattentiveness; need for loud tone communication suggest hearing loss.

There may be balance problems, delayed motor milestones, and speech language development, problems in school. The episodes of acute otitis media may recur with persisting OME in between. Tympanic membrane alteration eg posterior retraction pocket. The laterality (unilateral versus bilateral), duration of effusion and presence and severity of associated symptoms need documentation in medical record at each instance of OME.

OME and recurrent OM may be treated with myringotomy and insertion of tympanostomy tubes. The principle is to ventilate ME when ET function has failed. In most cases, adenoiditis causes ascending infection up the ET, its malfunction and obstruction. By ventilating the middle ear with grommet tube, effusion is cleared, helping mucosal inflammation to subside and better elimination of established pathogen biofilm. Adenoidectomy reduces burden of nasopharyngeal infection.

Persistent and recurrent otitis media is often addressed by adenoidectomy as initial surgical procedure. Such cases have bacterial colonization of postnasal space early in childhood. There is evidence that myringotomy and adenoidectomy can be effective treatment for OME.

Tymanostomy tube may cause early or late postoperative otorhhea. Adenoidectomy is thus preferred despite some risk of early post-op bleed and rare complications of velopharyngeal insufficiency or even nasopharyngeal stenosis. The procedure does more benefit than harm. Adenoidectomy is recommended for OME (unless child has an overt or submucous cleft palate), and reduces need for future operations by 50 percent. Benefit of adenoidectomy is apparent at age of 2 years and best in 3year and older, irrespective of adenoid size. There is no role for tonsillectomy.

**Tympanic membrane perforation**

Major consequence of tympanic membrane perforation is conductive hearing loss. Normal hearing is defined as an air–bone hearing gap of less than 25 dB. Hearing aids may be an alternative to cope with hearing disability but definitive therapy is surgery. Surgical closure is recommended in children with established chronic otitis media with perforation. Successful myringoplasty closes perforation and improves hearing. Ossicular damage requires specific correction with tympanoplasty.

Myringoplasty and tympanoplasty are valid for application at any age. Prior adenoidectomy predicts greater success of the functional outcomes. Myringoplasty is closure of the perforation of pars tensa of tympanic membrane, undertaken to restore hearing capability, mixed infections and persistent ear discharge. The graft material commonly used is temporalis fascia. Cartilage or perichondrium from tragus may also be used. Graft takes up and hearing improvement depends on size and site of perforation and surgical technique and skill. Age and gender of patient, past perforation history, duration of dry ear prior to surgery and presence or absence of infection during surgery are important determinants of success. Underlay technique of myringoplasty is simpler and widely used. Overlay technique suits repair of anterior quadrant perforations of tympanic membrane. Patients with small perforation display most hearing gain soon after healing. Patients with large perforation exhibit progressive gain in hearing function as closure of air–bone gap over more than year after surgery.

The authors declare no conflict of interest.

Nicotine redemption

Nicotine has a bad reputation as it is the chief ingredient of tobacco products. It is addictive and is responsible for the physical dependence associated with cigarette smoking. But it is a powerful nAChR agonist. This action may be beneficial in neurodegenerative disorders. In a new study done in mice, the effects of low, medium and high doses of nicotine on appetite, body weight, anxiety and nAChR levels were investigated. It was found that nicotine in high doses induced reduction in food intake and weight gain but caused elevated levels of nAChR without inducing anxiety. These results suggest a possible role for nicotine in the treatment of neurodegenerative disease and in prevention of aging of brain. However, nicotine use is forbidden in children and adolescents. The authors are careful to point out that this is definitely not an advertisement for tobacco smoking.

Calcium hydroxide has been used in dentistry for almost a century. Its mechanism of actions are achieved through the ionic dissociation of Ca(2+) and OH(–) ions and their effect on vital tissues, the induction of hard-tissue deposition and the antibacterial properties. Some of its indications include inter-appointment intracanal medicaments, endodontic sealers, pulp capping agents, apexification, pulpotomy and weeping canals. The purpose of this article is to review the properties, mechanism of action, applications, advantages, disadvantages and various indications for the use of calcium hydroxide in endodontics.

Key Words: Biomineral, Calcium hydroxide, Intracanal medicament, Weeping canal

Introduction

Bones and teeth are biocomposites that require controlled mineral deposition during their self-assembly to form tissues with unique mechanical properties. Biominerals such as calcium and phosphate synthetically produced or obtained from natural sources thus has an important function in the preventing demineralization and encouraging remineralization of hard tissues of the tooth along with the preservation and maintenance of the health of the pulp. Calcium hydroxide was introduced to the dental profession in 1921, Hermann demonstrated the formation of dentinal bridge in an exposed pulpal surface and it is now considered the “gold standard” for direct pulp capping agents. The use of the medication for root canal system disinfection has been supported to improve the treatment outcome as the complexity of the root anatomy makes more difficult their cleaning and shaping. Intracanal medications such as calcium hydroxide are used to reduce or eliminate bacteria located in the root canal system and prevent their proliferation between sessions. Since the introduction to dentistry of calcium hydroxide by Hermann (1920, 1930), this medicament has been indicated to promote healing in many clinical situations. However, the initial reference to its use has been attributed to Nygren (1838) for the treatment of the ‘fistula dentalis’, whilst Codman (1851) was the first to attempt to preserve the involved dental pulp. According to Cvek (1989) calcium hydroxide became more widely known in the 1930s through the pioneering work of Hermann (1936) and the introduction of this material in the United States (Teuscher & Zander 1938, Zander 1939). The first reports dealing with successful pulpal healing using calcium hydroxide appeared in the literature between 1934 and 1941. Since then, and mainly after the Second World War, the clinical indications for its use were expanded and now this chemical is considered the best medicament to induce hard tissue deposition and promote healing of vital pulpal and periapical tissues. Ca(OH)₂ is a white odorless powder with a molecular weight of 74.08. The material is chemically classified as a strong base with a high pH (12.5) and is only slightly soluble in water with a solubility of 1.2 g/l, at a temperature of 25˚C. The dissociation of Ca(OH)₂ into calcium and hydroxyl ions results in increased pH locally. High pH of Ca(OH)₂ causes irritation of the pulp tissue, which stimulates repair of dentin by the release of bioactive molecules such as Bone Morphogenic Protein and Transforming Growth Factor-Beta One.

Properties

- Structure:
  1. Arrangement= amorphous matrix, crystalline fillers.
  2. Bonding= covalent; ionic.
  3. Defects=pores, cracks.
  4. Setting reaction= acid base reaction.
- Physical Properties:
  1. L.C.T.E= low.
  2. Thermal conductivity= insulator.
  3. Electrical conductivity= insulator.
  4. pH=12.5-12.8.
- Chemical Properties:
  1. Solubility= 0.3-0.5
- Mechanical Properties:
  1. Elastic mod=588
  2. Compressive strength >24 hr=138
- Biologic Properties:
  1. Biocompatible.
Bactericidal Properties:
Ca(OH)_2 is bacteriocidal on contact. It must be in direct contact with the bacteria to be lethal. Ca(OH)_2 has been shown to be active and not active against E. faecalis and Pseudomonas aeruginosa. Asgary and Kamrani tested Ca(OH)_2 against Pseudomonas aeruginosa, E. faecalis, Staphylococcus aureus, and Escherichia coli and found it to inhibit growth of these bacteria.

Mechanism of action
Antimicrobial activity:
The antimicrobial activity of Ca(OH)_2 is related to the release of hydroxyl ions in an aqueous environment (Siqueira 2001). Hydroxyl ions are highly oxidant free radicals that show extreme reactivity with several biomolecules. This reactivity is high and indiscriminate, so this free radical rarely diffuses away from sites of generation (Siqueira & Lopes 1999). The lethal effects of hydroxyl ions on bacterial cells are probably due to the following mechanisms (Siqueira & Lopes 1999):
- damage to the bacterial cytoplasmic membrane;
- protein denaturation; and
- damage to the DNA.

Mineralization activity:
When used as a pulp-capping agent and in apexification cases, a calcified barrier may be induced by calcium hydroxide (Eda 1961). Because of the high pH of pure calcium hydroxide, a superficial layer of necrosis occurs in the pulp to a depth of up to 2 mm (Estrela & Holland 2009). Beyond this layer, only a mild inflammatory response is seen and, provided the operating field is kept free from bacteria when the material was placed, hard tissue may be formed (Estrela et al. 1995).

Applications
1. Intracanal Medicament: It is the most commonly used dressing for treatment of the vital pulp. It also plays a major role as an inter-visit dressing in the disinfection of the root canal system. Calcium hydroxide cannot be categorized as a conventional antiseptic, but it kills bacteria in root canal space. Calcium hydroxide is a slowly working antiseptic. Direct contact experiments in vitro require a 24 hour contact period for complete kill of enterococci. Calcium hydroxide not only kills bacteria, but it also reduces the effect of the remaining cell wall material. Polysaccharide. It has a wide range of antimicrobial activity against common endodontic pathogens, but is less effective against Enterococcus faecalis and Candida albicans. Calcium hydroxide is also an effective anti-endotoxin agent. However, its effect on microbial biofilms is controversial.

2. Endodontic Sealer: To be therapeutically effective calcium hydroxide must be dissociated into Ca++ and OH-. Therefore to be effective, an endodontic sealer based on calcium hydroxide must dissolve and the solid consequently lose content.

Applications 12
3. Pulp Capping Agent: Calcium hydroxide is generally accepted as the material of choice for pulp capping. Histologically there is a complete dentinal bridging with healthy radicular pulp under calcium hydroxide dressings. When calcium hydroxide is applied directly to pulp tissue there is necrosis of adjacent pulp tissue and an inflammation of contiguous tissue. Dentinal bridge formation occurs at the junction of necrotic tissue and vital inflamed tissue. Beneath the region of necrosis, cells of underlying pulp tissue differentiate into odontoblasts and elaborate dentin matrix.

4. Apexification: In apexification technique canal is cleaned and disinfected, when tooth is free of signs and symptoms of infection, the canal is dried and filled with stiff mix of calcium hydroxide and CMCP. Histologically there is formation of osteodentin after placement of calcium hydroxide paste. There appears to be a differentiation of adjacent connective tissue cells; there is also deposition of calcified tissue adjacent to the filling material.

5. Pulpotomy: It is the most recommended pulpotomy medicament for pulparly involved vital young permanent tooth with incomplete apices. It is acceptable because it promoted reparative dentin bridge formation and thus pulp vitality is maintained.

6. Weeping Canals: For such teeth dry the canals with sterile absorbent paper points and place calcium hydroxide in canal. Calcium hydroxide converts the acidic pH of periapical tissue in the weeping canal to basic pH.

Method of preparation
The easiest method to prepare a calcium hydroxide paste is to mix calcium hydroxide powder with water until the desired consistency is achieved.

Leonardo et al. (1982) stated that a paste prepared with water or other hydrosoluble non-viscous vehicle does not have good physicochemical properties, because it is not radio-opaque, is permeable to tissue fluids and is rendered soluble and resorbed from the periapical area and from within the root canal. For these and the following reasons, Leonardo et al. (1982) recommended the addition of other substances to the paste:
1. To maintain the paste consistency of the material which does not harden or set;
2. To improve flow;
3. To maintain the high pH of calcium hydroxide;
4. To improve radiopacity;
5. To make clinical use easier;
6. Not to alter the excellent biological properties of calcium hydroxide itself.

Composition of calcium hydroxide paste
Calcium hydroxide paste for use in endodontics is composed of the powder, a vehicle and a radiopacifier. Other substances may be added to improve physicochemical properties or the antibacterial action.
Vehicles

According to Fava (1991), the ideal vehicle should:
1. Allow a gradual and slow Ca²⁺ and OH⁻ ionic release;
2. Allow slow diffusion in the tissues with low solubility in tissue fluids;
3. Have no adverse effect on the induction of hard tissue deposition.

The vehicles mixed with Ca(OH)₂ powder play an important role in the overall dissociation process because they determine the velocity of ionic dissociation causing the paste to be solubilized and resorbed at various rates by the periapical tissues and from within the root canal. The lower the viscosity, the higher will be the ionic dissociation. The high molecular weight of common vehicles minimizes the dispersion of Ca(OH)₂ into the tissues and maintains the paste in the desired area for longer periods of time (Athanassiadis et al. 2007).

There are three main types of vehicles:

1. Water-soluble substances such as water, saline, anaesthetic solutions, carboxymethylcellulose, methylcellulose and Ringers solution.
2. Viscous vehicles such as glycerine, polyethylene glycol (PEG) and propylene glycol.
3. Oil-based vehicles such as olive oil, silicone oil, camphor (the oil of camphorated parachlorophenol), some fatty acids (including oleic, linoleic, and isostearic acids), eugenol and metacresylacetate (Fava & Saunders 1999).

Staehle et al. (1995) reported that an aqueous suspension allows a more efficient release of hydroxyl ions. According to Simon et al. (1995), distilled water or camphorated paramonochlorophenol result in better diffusion than phosphate buffered saline or propylene glycol.

Radiopacifier: Calcium hydroxide mixed with any of the quoted vehicles lacks radiopacity and is not easily seen radiographically. This is the main reason radiopaque materials are added to the paste, thereby allowing identification of lateral and accessory canals, resorptive defects, fractures and other structures (Smith & Woods 1983, AlacÉ am et al. 1990). A radiopacifier should have an atomic weight higher than calcium for radiopacity purposes (Tavano et al. 1978). Some examples of such substances are barium sulphate and bismuth, and other compounds containing iodine and bromine (AlacÉ am et al. 1990).

Characteristic of calcium hydroxide paste

When calcium hydroxide powder is mixed with a suitable vehicle, a paste is formed and, because the main component is calcium hydroxide, Maisto (1975) classified these formulations as alkaline pastes because of their high pH. According to some authors (Maisto 1975, Goldberg 1982, Leonardo et al. 1982), these pastes should have the following characteristics:

1. Composed mainly of calcium hydroxide which may be used in association with other substances to improve some of the physicochemical properties such as radiopacity, flow and consistency;
2. Non-setting;
3. Can be rendered soluble or resorbed within vital tissues either slowly or rapidly depending on the vehicle and other components;
4. May be prepared for use at the chairside or available as a proprietary paste;
5. Within the root canal system they are used only as a temporary dressing and not as a definitive filling material.

Advantages of Calcium hydroxide

- Initially bactericidal then bacteriostatic.
- Promotes healing and repair.
- High pH stimulates fibroblasts.
• Neutralizes low pH of acids.
• Stops internal resorption.
• Inexpensive and easy to use.

**Disadvantages of Calcium hydroxide**

• Does not exclusively stimulate dentinogenesis.
• Does exclusively stimulate reparative dentin.
• Associated with primary tooth resorption.
• May dissolve after one year with cavosurface dissolution.
• May degrade during acid etching.
• Degrades upon tooth flexure.
• Marginal failure with amalgam condensation.
• Does not adhere to dentin or resin restoration.

**Conclusion**

Calcium hydroxide is widely used material in endodontic treatment due to its high alkalinity and bactericidal properties. It is a material which is readily available, simple to prepare and restorable. Calcium hydroxide is still a material of choice which is widely being used for various reasons in Endodontics.

Case Report

**A Rare Case of Herpes Simplex Virus Type 2 Induced Acute Retinal Necrosis**

Stephen Sudhakar*, Charanya C**, Ananya A**

*Prof & HOD, **Post Graduate Student, Dept. of Ophthalmology, Chettinad Hospital & Research Institute, Chennai, India.

Corresponding author - Stephen Sudhakar (dr_stephen1978@yahoo.com)

Introduction

Acute retinal necrosis (ARN) is a rare but potentially devastating syndrome characterized by progressive peripheral necrotizing retinitis. It was first described in 1971. It is usually caused by Varicella zoster and occurs in immunocompetent individual. 

Progressive outer retinal necrosis (PORN) is also type of necrotizing retinitis and characterized by multifocal lesions without granular borders in deep retinal layers. The main difference between both ARN and PORN is ARN occurs in immunocompetent and PORN in immunocompromised and absence of inflammation in PORN.

Herpes simplex virus is a DNA virus belonging to herpes family is two types – type 1 and type 2. Herpes Simplex Virus 1 is transmitted by oral contact and direct contact. In eye it causes herpes keratitis which is the leading cause of corneal blindness in U.S.A. Herpes Simplex Virus 2 causes genital herpes and sexually transmitted. 3.7 billion people have Herpes Simplex Virus 1 and 417 million people have Herpes Simplex Virus 2 infection.

Case History

A 29 year old female came with complaints of defective vision in left eye for one week duration. There is a history of fever, vomiting and headache for 2 weeks for which she was admitted and treated. There is also history of joint pain. On examination, right eye appears to be normal with normal unaided visual acuity. Left eye anterior segment showed circumciliary congestion of conjunctiva with fine keratic precipitates in cornea and anterior chamber showing cells 3+. Patient’s best corrected visual acuity in left eye was 6/12. The patient was given topical steroids and was reviewed after 1 week. Patient vision worsened to 3/60 inspite of treatment with pupil sluggishly reacting to light. Fundus examination of right eye was within normal limits. Fundus examination of left eye showed hazy media due to vitreous inflammation. Vitreous cells were 2+. Optic disc showed edema with blurring of disc margins(Fig1). The superior retinal quadrant showed pale and thin retina with granular borders which are well demarcated(Fig 2). There was evidence of retinal vasculitis with sheathing of arteries and occluded peripheral retinal vessels in superior quadrant of retina(Fig 3). With the above clinical findings, a presumptive clinical diagnosis of acute retinal necrosis in the left eye was made. Routine blood investigations, ANA, RA factor VDRL, HIV serology, Mantoux, Chest X-ray were within normal limits.

Abstract

29 year old healthy female came with complaints of defective vision in left eye for one week duration along with pain, redness and floaters. On examination, patient was found to have pan uveitis, retinal vasculitis, vitritis and necrosis of the peripheral retina in the left eye. A diagnosis of acute retinal necrosis was made. PCR analysis of aqueous and vitreous revealed Herpes Simplex Virus type 2 which is a rare cause for acute retinal necrosis.

Key Words: Acute Retinal Necrosis, Immunocompetent, Herpes Simplex Type 2
Case Report
A Rare Case of Herpes Simplex Virus Type 2 Induced Acute Retinal Necrosis

Discussion
Acute Retinal Necrosis is caused by viral infection mostly by Varicella zoster virus or Type 1 Herpes Simplex. Type 2 Herpes Simplex Virus causing Acute Retinal Necrosis is very rare. American Uveitis Society defined ARN based on following clinical criteria:
1) One or more foci of retinal necrosis with discrete borders located in the peripheral retina
2) Rapid progression in the absence of antiviral therapy
3) Circumferential spread
4) Evidence of occlusive vasculopathy with arterial involvement
5) A prominent inflammatory reaction in the vitreous and anterior chambers

Our patient had all the above clinical findings and hence was diagnosed clinically as Acute Retinal Necrosis. The confirmation of organism is usually by Polymerase Chain Reaction with aqueous or vitreous samples. We went on to do a PCR analysis of aqueous and vitreous and it showed type 2 herpes simplex virus which is very rare. Rarely in non-responding cases is diagnostic vitrectomy or retinal biopsy needed.

Antiviral therapy can be given systemically as well as intravitreally. Commonly used systemic antiviral used are acyclovir, famciclovir, valacyclovir antiviral agents given intravitreally are ganciclovir (200 microgram/0.1 ml) foscarnet (1.2 mg/0.1ml). They are given in retinitis threatening macula or optic disc.

The patient completed the course of oral Valcyclovir 1gm TID for 6 weeks and her renal function was stable throughout the treatment. Intravenous anti-viral medications were not given as the patient is immunocompetent and had responded to oral valacyclovir. The patient is currently on regular follow up for recurrence of disease in both eyes.

Conclusion
Acute retinal necrosis is a severe ocular inflammatory syndrome in immunocompetent associated with poor visual outcome. It is commonly caused by Varicella zoster virus, Herpes Simplex virus type 1 and less commonly by Herpes simplex virus type 2 as in our case which was confirmed by PCR analysis of vitreous and aqueous samples. The patient responded well to oral Valacyclovir which was given for 6 weeks along with steroids. Retinal inflammation subsided, but retinal thinning still persisted as the retina was necrosed.

Patient is currently on follow up for recurrent involvement in same eye and for involvement of other eye. Photocoagulation of retina is planned in left eye for prevention of Retinal Detachment.

Spirituality Boost in a Nasal Spray

Are you troubled by your lack spirituality? Are you tempted to seek the guidance of a spiritual healer to fill that void? You are more likely to succeed in your goal if you bought a can of Oxytocin nasal spray instead. Oxytocin is a physiological hormone mainly involved in childbirth and breastfeeding. But it is also called “Cuddle hormone or love hormone” as it enhances maternal/social bonding, empathy and sexual pleasure. In a new random controlled study carried out on 83 males, researchers found that Oxytocin, when administered as nasal spray, enhanced the sense of spirituality in the study subjects when compared to those receiving only placebo. The effect was more marked in those subjects who had a particular genetic variant of CD38 gene, which is known to be involved in oxytocin release from hypothalamus. Whether the hormone has similar effect in women is not yet known and needs to be investigated. For the present, those men seeking spiritual high, can achieve that with Oxytocin nasal spray!

Case Report
Bisphosphonate Induced Recurrent Anterior Uveitis

Stephen Sudhakar*, Manoj Vasudevan**, Vigneshwaran***, Ananya A****

*Prof & HOD, ** Associate Professor, **** Post Graduate Student, Dept. of Ophthalmology, CHRI, *** Associate Professor, Dept. of General Medicine, Chettinad Hospital & Research Institute.

Introduction
Bisphosphonates are used to inhibit bone reabsorption in post-menopausal women and to manage hypercalcemia associated with osteolytic bone lesions1. It can cause both systemic and ocular inflammatory response. Ocular side effects range from conjunctivitis, episcleritis, scleritis, uveitis and rarely retrobulbar optic neuritis2. No case of unilateral or bilateral scleritis resolved until bisphosphonates therapy was discontinued. The mechanism is unclear. Proinflammatory cytokines such as TNF-alpha and IL-6 may play a role in pathogenesis of ocular inflammation3. Here we present a rare case of bisphosphonate induced recurrent anterior uveitis.

Case History
A 68 year old female presented to Ophthalmology OPD, Chettinad Hospital and Research Institute with chief complaints of defective vision, pain and redness in right eye since one day. History of similar complaints in both the eyes for past two years intermittently. The patient was a known diabetic since 2 years on regular follow up and treatment. The patient was on oral alendronate (150 mg every two weeks) since 2 years for postmenopausal osteoporosis.

On examination, anterior segment of right eye showed lid oedema, conjunctival congestion with circumcorneal congestion, flare and cells (3+), hyphema in the anterior chamber (Fig 1 & Fig 2). Visual acuity of right eye decreased to 6/12 with glasses. B scan of right eye was done which was in normal limits. Anterior segment of both eyes showed signs of previous attacks of anterior uveitis with pigment dispersion at the back of cornea and atrophic iris. Blood investigations were in normal limits except elevation of C reactive protein and ESR levels. Blood sugars were under control (HbA1c-5.2). A presumptive diagnosis of Bisphosphonates induced uveitis was made. The patient was advised to stop the drug immediately. The patient was started on topical cycloplegics and topical steroids. The patient vision improved to 6/9 within one week and hyphema resolved completely. Steroids were gradually tapered and no further attacks of uveitis were noted in a 6 month follow up.

Abstract
A 68 year old female patient presented to ophthalmology OPD with recurrent episodes of anterior uveitis in both eyes since 2 years. Routine uveitis work-up was found to be within normal limits except elevated ESR and CRP levels. The patient had been taking oral alendronate 150 mg every two weeks for the past two years, which correlated with the duration and onset of uveitis. Uveitis improved drastically on stoppage of the drug with no further evidence of uveitis for past 6 months in both eyes. Patient is currently on follow up.

Key Words: Anterior Uveitis, Hyphema, Bisphosphonates

Case Report Bisphosphonate Induced Recurrent Anterior Uveitis

Discussion

Bisphosphonates are used in osteoporosis to prevent bone resorption. Hypercalcaemia resulting from metastatic disease of bone, Paget’s disease, osteolytic cancers are treated with bisphosphonates. Bisphosphonates (nitrogen and non-nitrogen-containing) are known to cause ocular inflammation when given orally or intravenously, though intravenous use tend to cause earlier ocular inflammation. Ocular inflammation caused by pamidronate disodium has been reported more frequently than other bisphosphonates. Bisphosphonates activates specific T-cell groups which reduce bone resorption. Cytokine activation induces immunological reaction resulting in ocular inflammation. Discontinuation of Bisphosphonates and administration of steroid resulted in resolution of inflammation in many patients. Our patient was on oral alendronate (150 mg every 2 weeks) for the past two years during which she had recurrent episodes of non-granulomatous uveitis in both eyes. Her latest episode of uveitis resulted in hyphema and caused her defective vision. After the stoppage of alendronate, patient had no recurrence of uveitis in both eyes in 6 months follow up.

Conclusion

Ocular side effects of bisphosphonates though rare must be made to known to physicians and ophthalmologists and early diagnosis must be initiated for stoppage of the drug (Table 1). Less than 2% of patients develop systemic side effects which includes ocular inflammation, electrolyte imbalance, renal failure, nephrotic syndrome, maxillary and mandibular bone necrosis. For patients who develop ocular symptoms, prompt ophthalmologic evaluation is crucial to determine the safety of a subsequent bisphosphonate therapy. Increased C-reactive protein, ESR levels and leucopenia may be a non-specific indicator of Bisphosphonates induced uveitis as in our case. Patients who receive long-term bisphosphonate therapy should be evaluated at regular intervals for early signs of ocular inflammation, electrolyte imbalances and for hypocalcaemia.

Abstract
Myasthenia gravis, an acquired auto immune disease of the neuromuscular junction, has ophthalmic manifestations as integral part. Herewith we report a rare unilateral involvement of the eye in a 38 yrs old male. He presented with the drooping of right upper eyelid since two years, worsening by evening and after exertion. Though the blood investigations and Ach antibody titres were normal, he responded well to 1.5mg neostigmine intramuscularly.

Key Words: Ocular myasthenia gravis, Neostigmine

Introduction
Myasthenia gravis (MG) is an acquired auto-immune disease of the neuromuscular junction which causes rapid muscle fatigue and weakness. Ocular manifestations are an integral part of Myasthenia gravis. Ptosis and diplopia are the initial complaint in around 75% to 90% cases. Ocular MG, in which weakness remains confined to the ocular muscles only, is encountered in up to 17% to 58% of all myasthenics. Some less common or rare ocular signs like paradoxical reversal of ptosis, enhanced ptosis, total external ophthalmoplegia, internuclear ophthalmoplegia, chronic progressive external ophthalmoplegia and lid retraction contralateral to the ptotic eye. Although bilateralophthalmologic involvement of disease is quite common, it is rare to find a case of unilateral Ocular Myasthenia Gravis.

Case Report
A 38 year old male presented to Ophthalmology OPD, Chettinad Health and Research Institute with a chief complaint of drooping of right upper eyelid since two years which was worsened by evening and on excessive work. He has no other systemic illness and no ocular complaints of diplopia.

On examination, visual acuity was 6/6 and extra ocular movements were full. Right eye revealed ptosis was of 4mm, Bell’s phenomenon was normal, Levator palpebral action 7 mm by Berke’s method with rest of the anterior segment and posterior segment being normal. Anterior and posterior segments were found to be in normal limits in left eye except mild lid retraction. 'Ice pack test was positive. The routine blood investigations were found to be in normal limits except the mild elevation of ESR levels. USG abdomen and HRCT chest were found to be in normal limits. The acetyl choline receptor antibody titres were found to be in normal titres. The patient was subjected to neostigmine test after obtaining anaesthetic fitness and with cardiac monitoring. After injection neostigmine 1.5 mg intramuscularly, the ptosis showed significant improvement after 30 minutes, confirming the diagnosis of Unilateral Ocular Myasthenia gravis. Neurologist opinion was obtained and advised tablet Pyridostigmine 60 mg thrice daily 8.

Discussion
Myasthenia gravis is a disease characterized by fatigue and weakness of the striated muscle within the body. Although the exact cause is unknown it is thought to be an acquired autoimmune disorder the defect lies at the postsynaptic membrane. 70 percent of patients with myasthenia gravis have visual symptoms in the initial presentation Generally the female: male ratio in generalized myasthenia is 3:2 or higher. But on the contrary ocular myasthenia is more in especially after the age of 40 years. In addition, the average age of onset for generalized myasthenia is 33 years, while that of ocular myasthenia is 38 years. 2 Common clinical features seen in patients with ocular MG are ptosis (droopy eyelids), diplopia (double vision) and incomplete eye closure. Environmental, emotional, and physical factors also found to influence the symptoms for the patients. The major factors found to affect them are bright sunlight, extreme temperature, emotional stress, illness, surgery, menstruation, and pregnancy. Symptoms were found to be worse at the end of the day during the evenings or after exertion of the muscle.

Case Report
Unilateral Ocular Myasthenia Gravis

Elevated Ach receptor antibody confirms the diagnosis of Myasthenia gravis in 80% to 90% cases of Myasthenia gravis and 30-77% cases of Ocular myasthenia gravis. Of these patients, 30% will have autoantibodies against muscle specific kinase (anti MuSKAb) expressed on skeletal muscle. Patients who are negative for both Ach and MuSK antibodies are classified as “seronegative” Myasthenia gravis. CT scan should be done to rule out thymic hyperplasia. Thyroid function tests should be done to rule out autoimmune thyroid disease.

Treatment is chiefly medical and aims at improving muscle weakness (thereby alleviating symptoms of diplopia and ptosis), achieving disease remission, minimizing drug induced side effects, and slowing or preventing progression to generalized Myasthenia. Medications include cholinesterase inhibitors such as Mestinon, pyridostigmine, steroids such as Prednisone, or other immunosuppressants used alone or in combination. Other options include plasmapheresis, or IV IG therapy. These treatments offer only a temporary improvement and repeated treatments are necessary to sustain the effect. Supportive measures include the use of prisms or occlusion therapy for those with persistent diplopia and crutch glasses for severe ptosis.

Conclusion
Eventhough Myasthenia gravis is a common neuromuscular junction disorder. Ocular myasthenia in the early stages is often misdiagnosed. So clinicians should examine each case with a high degree of suspicion. The diagnosis can be made with simple clinical and pharmacological tests.

Abstract
We present here a case of thoracic aortic dissection requiring complex open and endovascular repairs in a 41 year old male bodybuilder in the context of recreational use of a sports supplement, Res 100, which is marketed as an anabolic steroid agent. He did not suffer from hypertension, aortic coarctation or atherosclerosis. He did not have any pre-existing aortic aneurysm or congenital aortic valve defects and had neither evidence of Marfan’s nor Turner’s syndrome. Genetic testing for chromosomal abnormalities was negative. Laboratory testing did not support inflammatory or infectious conditions. Additionally, the mean age of patients with acute aortic dissection is 62 years old as per the International Registry of Acute Aortic Dissection, which is in contrast with our patient’s 41 years of age. However, anecdotal reports of dissection in bodybuilders feature ages ranging from 19 to 53 years old. These reports also found strenuous activity to precede dissection, our case demonstrates symptom onset during minimal exertion and a potential link to performance enhancing drugs. This case highlights the variability in the risk factor profile for aortic dissection pathology.

Key Words: Aortic Dissection, Body Builders, Res 100

Case Report
A 41-year-old male weightlifter presented to the emergency department after experiencing chest pain radiating to his jaw whilst vacuuming, on the background of recreational use of ‘Res 100’, a compound used by bodybuilders to increase autologous testosterone and inhibit oestrogen. He was otherwise well with no history or family history of aortic disease. His blood pressure was initially 169/92 mmHg with the rest of his vital signs being within normal limits.

Echocardiogram revealed an aortic dissection rupturing into the pericardium with tamponade. CT angiography demonstrated extensive aortic dissection involving the ascending aorta, arch and the descending aorta; and ending at the renal arteries (Fig1). There were no radiological or clinical signs of compromised perfusion distally.

He underwent emergency surgery for an ascending aortic repair an hour later. Cannulation for cardiopulmonary bypass was via the right femoral artery and vein. His pericardial effusion was evacuated. A primary tear was identified within the proximal ascending aorta and no intimal tear was seen within the arch. The ascending aorta was replaced with a 30mm Dacron graft, with resuspension of the aortic valve. On table DSA then revealed adequate perfusion of cerebral and visceral segments via the true lumen.

On his first post-operative day, increasing lactate and creatinine levels were noted and a CTA was performed which showed near total obliteration of the true lumen in the proximal descending aorta due to a pressurised false lumen.

He was returned to the operating theatre and had a redo median sternotomy with debranching of the innominate and left common carotid arteries from the ascending aortic graft to provide a sufficient landing zone for a stent graft. A thoracic endovascular stent graft was deployed from within the ascending aortic graft to the mid-descending thoracic aorta. An uncovered self-expanding stent was deployed down to the origin of the coeliac axis to scaffold the true lumen. He was then transferred to the intensive care unit in a haemodynamically stable state. Subsequently, his visceral perfusion stabilised. The patient was discharged home three weeks postoperatively.

Discussion
Aortic dissection is a rare and potentially lethal condition. A tear in the aortic intimal layer creates an intramural lumen into which high velocity blood flow can track, creating a false lumen, capable of causing severe morbidity and mortality. Known risk factors for this condition include connective tissue abnormalities and/or systemic hypertension. More recent associations include strenuous activities and substance abuse.

There is a large evidence base correlating strenuous activities with aortic dissection. Extreme haemodynamic loading is observed in activities such as weight-lifting where blood pressure has been reported to reach 480/350 mm Hg. Elefteriades et al, demonstrated acute aortic dissection in the setting of strength training in men aged 19-53. Additionally, multiple case reports describe aortic dissection in otherwise healthy adult male body-builders and one case report has...
This case describes a patient with an unusual history and presentation. He is young, with no history of aortic disease or hypertension. He was 41 years of age at onset in contrast with IRAD’s average age of 62 years. His onset of symptoms occurred with minimal exertion and he was concurrently taking a testosterone supplement. This case also highlights the appropriate combination of cardiac surgical and endovascular skills to culminate in a good outcome in a time period where branched stent grafts are not available for the arch.

Just Like adults

Prevailing understanding is that the adults and the children are different when it comes to making moral judgements. The adults appear to give greater emphasis to intention rather than the outcome of an action. For example, hurting someone intentionally is considered morally worse than accidentally doing the same. But the children are believed to base their moral judgements on the outcome of an action rather than on intention. But this has been challenged in a recent study involving 138 children aged between 4 and 8 and 31 adults in which the study subjects were told, and questioned about, four stories about accidental (good intention/bad outcome) and attempted (Bad intention/good outcome) harms; but unlike in earlier studies, the authors rephrased the acceptability questions. The results were dramatically different from the earlier conclusions. Children above the age of 4 made moral judgements much like adults i.e. they too based their judgments on intention than on outcome.

- Dr. K. Ramesh Rao

Answer to: Diagnose the condition

ECG shows bradycardia with obvious QRS complexes at the rate of 30/min. Possibility could be a Junctional rhythm but with low rate. No obvious sinus P waves are seen. But retrogradely conducted P wave can be seen after each QRS complex. These features are suggestive of complete Sinus Arrest (SICK SINUS SYNDROME) with escape rhythm. This patient did not respond to Atropine. Probably the site of impulse generation is His bundle.

Spontaneous Recanalization of an Occluded Internal Carotid Artery

Alexandra Matthews, Hansraj Riteesh Bookun, Andrew Cheng, Emily Stevens

Junior Doctor, The Geelong University Hospital, Geelong, Australia

My name is Alex Matthews and I am currently working as a Junior Doctor for Barwon Health in Geelong, Victoria. Throughout the course of my studies I have maintained an interest in surgery, critical care and pre-hospital medicine. Whilst rotating through different areas of the hospital environment I have enjoyed the variety of patient presentations and unusual cases across each specialty. In order to continue my learning and contribute in my field I aim to publish further studies of interest which will influence practice and improve patient outcomes.

Corresponding author - Dr. Hansraj Riteesh Bookun (riteesh.bookun@gmail.com)

Abstract

We describe here a case of spontaneous recanalization of a left occluded Internal Carotid Artery (ICA) on the background of a previous Carotid Endarterectomy (CEA) on the contralateral symptomatic side. This rare event with only anecdotal evidence describing its incidence and natural history was picked up with ultrasound scanning. Initially, only trickle flow was demonstrated and after 12 months, the stenosis in the left internal carotid artery was graded as less than 50% on ultrasound. Our report highlights the importance of following up carotid system lesions and contributes to the discussion of how such events should be managed.

Key Words: Internal Carotid Artery (ICA), Carotid Endarterectomy (CEA)

Case Report

Mr EL is a 70 year old man who presented to the Vascular Surgery Outpatient Clinic for routine surveillance of his carotid artery disease; having previously undergone a right CEA in June 2011. This was in the setting of a 70-79% symptomatic stenosis of the right ICA and an occluded left ICA. He suffered from a left middle cerebral artery territory stroke in January 2011. Mr EL maintains a complex past medical history including radical prostatectomy and abdominoperineal resection for bowel cancer. He also has regular surveillance for a 44mm infra-renal abdominal aortic aneurysm and is treated pharmaceutically for hypertension, hyperlipidaemia, and type 2 diabetes mellitus.

Mr EL is an ex-smoker with a 40 pack year history. He drinks moderate amounts of alcohol and lives independently with his wife. Mr EL was followed up 4 weeks post-operatively in July 2011. He underwent carotid ultrasound studies which demonstrated no stenosis in the right ICA and occlusion of the left ICA. He has since been followed up annually as an outpatient and has experienced no symptom of cerebral ischaemia. Routine ultrasound surveillance of the carotid arteries in July 2012 and August 2013 reported no change. However in August 2014 carotid ultrasound of the left ICA demonstrated a trickle of flow, while the right ICA remained unchanged. This new finding was discussed during clinic with the vascular consultant and repeat surveillance was arranged in 12 months’ time.

Mr EL’s latest carotid ultrasound study from August 2015, (50 months after contralateral surgical intervention) demonstrates that the left internal carotid artery is now open with ≤50% stenosis, while the right ICA remains unchanged. Each carotid ultrasound report was undertaken at the same location but was reported by a different radiologist and undertaken by different ultrasound technologists. There is currently no explanation or clear aetiology which can account for the late spontaneous recanalization of Mr EL’s left ICA.

Mr EL decided not to have any further follow-up or surveillance in regards to his vascular disease and does not want open arterial or endovascular repair should a problem arise in the future. He was subsequently discharged from clinic with no further plans for medical imaging.

Discussion

Spontaneous recanalization of the internal carotid artery is not uncommon in the acute phase. However late spontaneous recanalization remains rare with only anecdotal evidence including five similar case studies and one prospective cohort study published within the last 10 years. The imaging modality during follow-up surveillance is varied with ultrasound (US), magnetic resonance angiogram (MRA) and computerized tomographic angiography (CTA) all routinely used. Despite the increased cost and risk associated with MRA and CTA these are both commonly selected instead of US imaging. A recent study demonstrated that US equals the accuracy of CTA for carotid artery disease surveillance and given its clear advantages should be the imaging modality of choice.

A review of the literature also demonstrates a wide range of clinical follow-up times for patients with contralateral carotid artery occlusion, which makes assessing the time course of recanalization difficult. However, the likelihood of this occurring does decrease with time, highlighting that older atheroembolic clot is more resistant to recanalization. There are numerous hypotheses to explain spontaneous recanalization in the acute setting; however the aetiology behind chronically occluded carotid arteries remains known.
The left ICA is completely occluded. No stenosis of the left CCA or origin of the ECA.
2014 Carotid Ultrasound: A normal appearance of the left CCA. Whereas previously the left ICA was thought to be occluded, there appears to be trickle flow through it on today’s examination. Normal directional flow of the left vertebral artery.
A prospective study demonstrated acute phase recanalization occurring in up to 33% of patients within 7 days of internal carotid artery occlusion. Further prospective analysis of a larger patient cohort with carotid artery dissection demonstrated that spontaneous recanalization was most likely to occur in the first 6 months. Camporese et al. demonstrated within a sample size of 696 patients with chronic ICA occlusion that only 2.3% (16 patients) would go on to have spontaneous recanalization over 38 months, therefore highlighting the lower rates of recanalization in the late setting. Within the individual cases studies identified, all five patients underwent successful endarterectomy following late spontaneous recanalization. However, the 16 patients identified by Camporese et al. did not undergo further surgical intervention and demonstrated benign clinical outcomes after mean follow-up times of 66.2 months. This outcome is also reflected in our case study as Mr EL experienced no further neurological symptoms in the 12 months following initial identification of spontaneous recanalization. These findings therefore question the clinical benefit and cost of surgical intervention following late spontaneous recanalization and therefore the benefit of regular surveillance imaging in chronic asymptomatic carotid artery occlusions. More research is required to determine the best timeline for follow-up imaging in order to maximise the cost-benefit ratio and avoid potentially unnecessary surgical intervention in patients with internal carotid artery occlusion.

Vascular endothelial growth factor antagonists play an important part in treatment of retinal disorders. To know more about this, a brief explanation of what is vascular endothelial growth factor is necessary. VEGF is a protein which causes vasculogenesis and angiogenesis. Vasculogenesis is important in development of vessels in embryo whereas angiogenesis plays a part in formation of collateral circulation in ischaemia.

VEGF is a type of growth factor. Increased presence in body can lead to diseases. This happens in carcinoma, which leads to increased growth and metastasis. Similarly presence of VEGF causes vascular diseases in retina due to diabetes and Age related macular degeneration. There are five isoforms of VEGF, A, B, C, D and fifth is a placental growth factor. VEGF A is important in angiogenesis after hypoxia. VEGF- B plays an important part in myocardial vasculature, other factors are involved in lymphangiogenesis.

These factors bind to tyrosine kinase receptors on cell surface and become activated by transphosphorylation, which causes vasculogenesis, angiogenesis and lymphangiogenesis. Hypoxia stimulates release of VEGF- A which in turn stimulates angiogenesis. In diabetic retinopathy, hypoxia due to retinal ischaemia releases VEGF which leads to neovascularisation of retina leading to vitreous hemorrhage and later trachional retinal detachment. It also plays a part in wet form of Age related macular degeneration.

VEGF antagonists has become a common method of treatment of neovascularisation of retina due to diabetes or other disorders, in vascular occlusion leading to macular edema, Age related degeneration and Neovascular glaucoma. They are also used in macular edema, neovascularisation due to branch retinal vein occlusion, central retinal vein occlusion. Recently they are used in retinopathy of prematurity to prevent progression of retinopathy. They block VEGF and reduce formation of harmful new vessels and there by decrease leakage and retinal edema, It is given as intravitreal injections. There are many anti- VEGF like bevacizumab, Ranibizumab, Pegaptanib, aflibercept, Anecortave acetate. Commonly used drugs are Ranibizumab, Bevacizumab and Aflibercept.

Bevacizumab (Avastin) is a humanized monoclonal antibody to all isoforms of VEGF. It was initially used for colorectal cancer metastasis. It binds directly to VEGF and forms a protein complex which inhibits further action of VEGF. It is used as off label drug in dose of 1.25 mg in 0.05 ml as intravitreal injection every 4-6 weeks. It is not approved by FDA. Intra-vitreal low dose of 0.375mg in 0.03 ml is used in retinopathy of prematurity with good outcome.

Aflibercept ( Trap Eye) is similar to Bevacizumab and Ranizumab. It is a fusionprotein with portion of receptors of VEGF (R-1, R-2). It has FDA approval for use in wet ARMD and is also used in macular edema due to diabetes and vascular occlusions. It is given as 2mg in 0.05 ml every 4 weeks for 3 months and once every 2 months later. All these drugs given by intra-vitreal injections can lead to floaters, increased intra-ocular pressure and rarely lead to endophthalmitis and retinal detachment. Since Bevacizumab half life is more(20 days) compared to Ranibizumab the chance of systemic side effects like stroke was found to higher.

Pegaptanib is a single strand nucleic acid that binds to VEGF 165, which is important in angiogenesis. It is used as 0.3 mg injection once every 6 weeks.

Bevacizumab (Avastin) is a humanized monoclonal antibody to all isoforms of VEGF. It was initially used for colorectal cancer metastasis. It binds directly to VEGF and forms a protein complex which inhibits further action of VEGF. It is used as off label drug in dose of 1.25 mg in 0.05 ml as intravitreal injection every 4-6 weeks. It is not approved by FDA. Intra-vitreal low dose of 0.375mg in 0.03 ml is used in retinopathy of prematurity with good outcome6.

Aflibercept ( Trap Eye) is similar to Bevacizumab and Ranizumab. It is a fusionprotein with portion of receptors of VEGF (R-1, R-2). It has FDA approval for use in wet ARMD and is also used in macular edema due to diabetes and vascular occlusions. It is given as 2mg in 0.05 ml every 4 weeks for 3 months and once every 2 months later. All these drugs given by intra-vitreal injections can lead to floaters, increased intra-ocular pressure and rarely lead to endophthalmitis and retinal detachment. Since Bevacizumab half life is more(20 days) compared to Ranibizumab the chance of systemic side effects like stroke was found to higher.
Ranibizumab (Lucentis) is a f-ab fragment of Bevacizumab. It is a monoclonal antibody fragment with strong binding to VEGF-A. It is given as 0.5 mg in 0.05 ml every 4-6 weeks as intra-vitreal injection.

In spite of limitations and cost, the advent of anti-VEGF has become a boon for patients to reduce severe visual loss. Newer anti-VEGF are being tested to get better results compared to Ranibizumab and Bevacizumab.

Conclusions

In spite of limitations and cost, the advent of anti-VEGF has become a boon for patients to reduce severe visual loss. Newer anti-VEGF are being tested to get better results compared to Ranibizumab and Bevacizumab.

History of Intra Ocular Lens

Shankar C*

*Associate professor, Dept of Ophthalmology, Chettinad Hospital & Research Institute, Chennai, India.

Corresponding author - Shankar C (shankar.chokkalingam@gmail.com)

History

Human crystalline lens is a transparent structure in eye, which along with cornea helps in focusing of light on retina. As ageing occurs this transparency is lost leading to formation of cataract. Even though cataract surgery was practiced 2000 years ago, modern cataract surgery started only 50 years back. In the past opaque cataractous lens was removed leaving the patient with compromised vision after surgery. Italian scientist Tadini in 18th century first considered intraocular lens implantation. In 1795 Casamata implanted an glass intraocular lens with poor outcome.

In 1949, Sir Harold Ridley first implanted the successful intraocular lens in London. This was due to the curiosity of his student who commented to Ridley that he did not replace anything after removing the cataract. At the same time Ridley was treating many World War II fighter pilots who had shattered windshield of cockpit in eyes, which did not cause reaction as a foreign body. This made him use this material called polyethyl methacrylate (PMMA) for intraocular lens which was found to be accepted well by the eye. This started the journey of IOL.

![Fig1: Sir Harold Ridley](image1)

![Ridley Posterior Chamber Lens 1949](image2)

Development

Development of IOL was with great success and disasters. Major development took place during seventies by Dr. Binkhorst, Dr. Worst in Europe and Dr. Shearing in America. They removed cataract leaving behind the lens capsule and implanting the IOL in the bag which improved the outcome dramatically. At the same time Dr. Charles Kelman was developing phacoemulsification, a new method of removing cataract through a small incision which paved way for development of foldable lens which when implanted unfolds within the eye giving better visual outcome.

Improved surgical techniques led to the development of IOL. The generation in which it occurred is described as 1st generation – Posterior chamber IOL 2nd generation – Anterior chamber IOL 3rd generation – Iris supported IOLs 4th generation – Anterior chamber Kelman IOL 5th generation – again Posterior chamber IOL 6th generation – from 1990 till date the newer IOL

![Fig 2: 2nd Generation IOLs](image3)
The search for ideal IOL is still on. IOL has evolved from replacement for cataractous lens to cosmetic refractive surgery. The outcome of surgery is determined by the pre and post operative astigmatism, and loss of accommodation due to the procedure. The patient after surgery has only proper distant vision with compromised near vision due to loss of accommodation.

Premium IOL

Newer premium IOL have redefined the way patient sees after surgery. The change from simple rigid PMMA lens which has to be implanted through a large incision to foldable lens being implanted through small incisions. These lenses are made of hydrophilic, hydrophobic acrylic material and silicone which can be folded or rolled.

Aspheric lenses where the edges of lens are flattened to reduce the aberration induced by regular lenses, to lenses with yellow chromophores which prevents damage to eye by ultra-violet light. Toric lenses are available which can overcome astigmatism and give clear vision with good contrast sensitivity. Multifocal lenses (Restor, Crystallens) have redefined surgery leading to better distance, intermediate and near vision (fig5). Myopic patients with high refractive error can be corrected with Phakic IOL which can be implanted over the normal clear lens leading to better vision (fig6). This has made IOL has refractive surgery counterpart.

Patients with low vision due to retinal problems can have telescopic IOL implanted which improve distant vision and used as low visual aids. This lens was first discovered by Dr. Lipshitz. He later modified this with mirrors to improve peripheral field and called it as Telescopic macular implant (fig7).

Future

Light adjustable IOL have also rapid strides in improvement. After IOL has been implanted the curvature of the IOL can be altered by application of laser. The search for better IOL with youthful vision is still leading the charge.

Instruction to Authors

The following are the uniform requirements for manuscripts submitted to the Chettinad Health City Medical Journal, which are in accordance with “Uniform requirements for Manuscripts submitted to Biomedical Journal” developed by International Committee of Medical Journal Editors (October 2001).

The manuscripts are to be sent as hard copies or submitted online to the Chief Editor:
Dr. N. Pandiyan,
Chief Consultant,
Department of Andrology & Reproductive Medicine,
Chettinad Health City,
Rajiv Gandhi Salai, (OMR, Chennai),
Kelambakkam, Kanchipuram Dist, Tamil Nadu 603 103 India.
Telephone: +91 (0)44 4742 8300.
Fax: +91 (0)44 4741 1011.
E-mail: pandiyan1@yahoo.com

The Editorial Process
The submitted manuscripts are taken up for review for possible publication assuming that they have not been simultaneously submitted or already accepted or published elsewhere. The initial review is conducted by the Editors. Manuscripts lacking significant originality, important message and those with serious flaws are rejected. The unaccepted manuscripts will not be returned. The other manuscripts are sent to two or more experts in the field for review and they are blinded for the identity of the contributors. The reviewers’ comments and acceptance or rejection of the manuscript will be informed to the contributors in 8 to 10 weeks. The accepted articles will be copy edited for format, spelling, grammar, punctuation, etc.

Types of Manuscripts and word limits
Original articles: This includes case series, randomised control trials, interventional studies, studies involving screening and diagnostic procedures, studies of outcome analysis, studies involving cost-effective analysis and surveys with high response rate. Word limit is 2500 excluding references and abstract. Review articles: This includes systematic critical assessment of literature and other data sources. Word limit is 3000 excluding references and abstract.
Case reports: This includes report of new cases, very rare cases and very interesting cases. There should not be just reporting of cases; but their clinical significance or implications should be emphasized. Word limit is 1000 excluding references and abstract; with up to 10 references.
Letter to the Editor: This includes short decisive observations, including brief reporting of rare and interesting cases. Word limit is 400 with up to 4 references.
Other Sections: Include Editorials, Perspective articles, History articles, Class room articles, which are by invitation from the Chief Editor.
Limits for number of images and tables: The number of tables and figures is limited to one per 500 words for all categories of manuscripts.
The templates for all types of manuscripts are available in the Journal’s website and authors are requested to use them.

Authorship criteria
Authorship should be based on substantial contributions to:
1) to concept and design or data acquisition or data analysis and data interpretation;
2) preparation of manuscript, critical revision and contribution to the intellectual content;
3) final approval of the manuscript version to be published..

Mere fund acquisition for the study or data collection or general supervision of the research project do not qualify for authorship.

All the authors must have contributed substantially to the work and must be able to take responsibility of the respective portions of their contributions.

The authors should named in the order of their relative contribution towards the study or the manuscript writing. This order cannot be changed after submission of the manuscript without the written consent from all the authors.

Number of authors
1) Original papers: Maximum of six from a single institution.
2) Case reports and review articles: Maximum of four.
3) Images and letter to editor: Maximum of three.
There must be a written justification if the number of authors exceeds these limits.

Sending the Manuscript to the Journal
The manuscript enclosed with covering letter and contributors’ form signed by all the authors with the photographs, should be sent as a soft copy to the Chief Editor. However, the authors are encouraged to send the manuscripts along with the above enclosures as E-mail attachment to the Chief Editor. The covering letter must include the undertaking that the manuscript has not been simultaneously submitted/ accepted/ published elsewhere. Conflict of interest if any in the form of financial or other relationship also should be disclosed. Copies of any permission to reproduce already published material including illustrations or photographs and consent for publication of identifiable material should be sent along with the manuscript.

Contact details of the Chief Editor:
Dr. N. Pandiyan,
Chief Consultant,
Department of Andrology & Reproductive Medicine,
Chettinad Health City,
Rajiv Gandhi Salai, (OMR, Chennai),
Kelambakkam, Kanchipuram Dist,
Tamil Nadu 603 103 India.
Telephone: +91 (0)44 4742 8300.
Fax: +91 (0)44 4741 1011.
E-mail: pandiyan1@yahoo.com

Preparation of the Manuscript
Font style and size: Time New Roman Size 12 for the text and 14 for the titles.
Double spacing without justifying.
The language and spelling style should be American English.
Title Page
This should contain:
- Title of the article (which should be short, relevant to the manuscript and informative)
- Type of the article (Original paper/review article/case report, etc.)
- Running title (short title) with less than 50 characters
- Names of authors (Name followed by initials/Last name, First name and initials of middle name) with the highest academic degree. Prefixes like Dr, Prof, etc. are avoided.
- The name of the department(s) and institution(s) where the work has been carried out.
- Corresponding author’s name, address, phone number and e-mail address.
- Total number of pages, table, photographs and word count for the text (excluding abstract and references).
- Sources of support/grant/equipment support, etc., if any.
- If already presented in a conference/meeting, name of the conference/meeting, place and date of presentation.

Abstract Page
- This should carry the full title of the manuscript and abstract.
- The word limit for the abstract is 250 for original articles/review articles, 150 for case reports.
- The abstracts are structured with introduction and aim, methods and materials, results and conclusions. Key words 3 to 10 are provided below abstract

Manuscript Pages:
Introduction
This should state the purpose of the study/article and the basis and rationale for the study.

Methods
- This should state nature of study - observational/experimental/trial, etc., whether prospective/retrospective.
- Selection of the subjects (patient/experimental animals) including controls.
- Details of the methods, apparatus (with the manufacturers name and address) and procedures.
- References should be quoted for established methods including statistical methods.
- New or less known methods should be described in detail with the rationale and limitations
- Generic names of drugs and chemicals used, including dose, route of administration should be stated.

- Reports of human studies should state that the procedures in accordance with the ethical standards of the responsible Institutional/Regional Ethical Committee on human studies and with the Helsinki Declaration, 1975 revised in 2000 (http://www.wma.net/e/policy/17-c_e.html). Patients’ identity including name, initials, hospital number, etc. shall not be disclosed.
- Reports involving animal experimentation shall state about the approval from Institutional Ethical Committee and adherence to the national law on the care and use of laboratory animals.
- Statistical methods used should be stated in detail.

Results
The results are shown in sequence in the form of text, tables/illustrations, wherever required. The data shown in the tables shall not be repeated in the text. Only important observations are summarized/emphasized.

Discussion
- New and important aspects of the study and the conclusions drawn from them and the implications for the future research are stated.
- There shall not be any repetition of the statements and data from the introduction and results section.
- The observations and conclusions of this study are compared and related to the other similar or relevant studies.
- False and unsubstantiated claims on cost or economic benefits shall be avoided.
- New hypotheses drawn from the study shall be stated and labeled as such, if required.

Acknowledgements
This shall be at last page of the manuscript. This may include:
1) General support from faculty that need acknowledging, not amounting to authorship.
2) Technical help
3) Financial and material support with the actual nature of support.

References
- Numbering is done consecutively in the text (not in alphabetical order)
- The references are identified in the text, tables and legends by Arabic numerals in superscript.
- The titles of the journals shall be mentioned in the abbreviated form as per the style used in the Index Medicus. Complete name of the journal is stated for non-indexed journals.
- Abstracts shall not be used as references.

Commonly cited types of references are shown below:

The tables and charts are provided at the appropriate place in the text and not at the end of the manuscript.

**Protection of Patients’ Rights to Privacy**

Identifying information shall not be published in written descriptions, photographs, CT scans, etc., and pedigrees; if the information is essential for scientific purposes written informed consent is required from the patient or guardian. Informed consent for this purpose requires that the patient be shown the manuscript to be published. When informed consent has been obtained, it should be indicated in the article and copy of the consent should be attached with the covering letter.

**Reprints**

Reprints are not provided by the Journal.

**Copyrights**

The Editorial board has the copyright of the literary content of the Journal. However, all users are permitted free access to and license to copy and use the work for non-commercial purpose with proper acknowledgment of the authorship and ownership rights.

The format of the Covering letter, Contributor’s form, templates for various types of manuscripts are available in the website and the authors are requested to download and use the same.

---

**Tables**

- Tables shall be self-explanatory and shall not repeated in text.
- Tables shall have not more than 10 columns and 25 rows.
- Tables are numbered in Arabic numerals consecutively in their order of citation in text
- A brief title is given for each table.
- Abbreviations used in the table shall be explained in the foot notes
- Tables borrowed, adapted or modified from other sources shall be duly acknowledged after due permission.

**Illustrations (Figures)**

- Good quality glossy color photo prints 4”X6” duly numbered and labeled are submitted with hard copy of the manuscript.
- For on line submissions, jpeg is the most suitable format, though the other formats (tiff, gif) are also acceptable.
- For already published figures, due permission shall be obtained and the same acknowledged in the manuscript.

**Legends for Illustrations**

- Figures are numbered in Arabic numerals and legends typed with double spacing with word limit of 40.
- When symbols, arrows or letters are used to identify parts of the illustrations, each one is explained in the legend.
- The internal scale, magnification and the method of staining are mentioned in photomicrographs.
DEPARTMENT OF PAEDIATRICS

CHETTINAD PEDICON - 2016
“UPDATES IN PEDIATRIC PRACTICE”

Date: 26th March, 2016
I. Under Graduate Courses
- M.B.B.S. (4½ years + 1 year internship)
- B.Sc. (Allied Health Sciences) (3 years + 1 year internship)
- B.Sc. (Medical Bionanotechnology) (3 years)
- B.Sc. (Medical Biotechnology) (3 years)
- B.Sc. (Medical Genetics) (3 years)

II. Post Graduate Courses

Medical Post Graduate Courses -
M.D. Pre and Para Clinical (3 years)
- M.D. (Anatomy)
- M.D. (Physiology)
- M.D. (Biochemistry)
- M.D. (Pathology)
- M.D. (Microbiology)
- M.D. (Pharmacology)
- M.D. (Community Medicine)

Medical Post Graduate Courses -
M.D./M.S. Clinical Courses (3 years)
- M.D. (General Medicine)
- M.D. (Anesthesiology)
- M.D. (Dermatology, Venerology and Leprosy)
- M.D. (Respiratory Medicine)
- M.S. (Orthopedics)
- M.S. (Ophthalmology)
- M.D. (Paediatrics)
- M.D. (Psychiatry)
- M.D. (Radio-diagnosis)
- M.S. (Otorhinolaryngology)
- M.S. (General Surgery)
- M.S. (Obstetrics and Gynecology)

Post Graduate Courses (2 years)
- M.Sc. (Tissue Engineering & Regenerative Medicine)
- M.Sc. (Medical Genetics & Molecular Diagnostics)
- M.Sc. (Medical Bionanotechnology)
- M.Sc. (Medical Biotechnology)
- M.Sc. (Clinical Research & Experimental Medicine)
- M.Sc. (Marine Pharmacology)

- M.Sc. (Human Nutrition)
- M.Sc. (Occupational Health & Industrial Safety)
- M.Sc. (Health & Yoga)
- M.Sc. (Computational Biology)
- M.Sc. (Bioinformatics)
- M.Sc. (Counseling Psychology)
- M.Sc. (Pharmaceutical Chemistry)

Post Graduate - Super Speciality Courses
D.M. / M.Ch Courses (3 years)
- D.M. (Cardiology)
- D.M. (Neurology)
- D.M. (Neonatology)
- D.M. (Gastroenterology)
- M.Ch. (Cardio Vascular & Thoracic Surgery)
- M.Ch. (Neuro Surgery)
- M.Ch. (Urology)

- M.Sc. - (Allied Health Sciences) (2 years)
  1. (Echocardiography & Cardiovascular Imaging Technology)
  2. (Radiology and Imaging Science Technology)

Post Graduate Courses in Nursing (2 years)
- M.Sc. Medical Surgical Nursing - (Cardio Vascular and Thoracic Nursing)

III. POSTGRADUATE DIPLOMA COURSES
- Postgraduate Diploma in Clinical Embryology (1 year)

IV. NURSING COURSES
- B.Sc. (Nursing) (4 years)
- Post Basic B.Sc Nursing (2 years)

V. Ph.D Program
- (1) Ph.D CARE Fellowship (JRF) Full time & Part time. Ph.D. Under the Faculty of Medicine, Nursing & Allied Health Sciences.
- (2) Post Doctoral Fellowship
